| Alternative 4: Pump and Treat | - Groundwater is not currently used, nor expected to be used in the future, as potable water; the area is served by municipal water supply system.<br>- Three CEAs will provide notice to future receptors that groundwater is not suitable for potable water.<br>- Groundwater ECs are in place to prevent groundwater from impacting soil remediation areas. | - Comprehensive and permanent contaminant reduction and mass removal.<br>- Controls the mass flux leaving the site boundary for as long as pumping continues. | - Pump and Treat is effective and provides permanent mass removal, but only within the zone of influence of the extraction well.<br>- Moderate-term monitoring | - Based on estimated number of extraction wells expected necessary to achieve the remedial goal and objectives, this alternative is not compatible with the redevelopment plan. | - Implementable.<br>- Pump and treat is a widely used alternative at contaminated groundwater sites.<br>- If alternative is constructed on properties not owned by PPG, access agreements will be necessary. | High | - Likely acceptable.<br>- Permanence of the remediation will be monitored. | 21 | Pump and treat is recommended for mass removal and plume stabilization. Pump and treat could be paired with another remedial technology such as In-situ Anerobic Bioprecipitation (ISAB) or ISCR to expedite the remediation. |

**Table 5-1**
**Comparative Analysis of Groundwater Remedial Alternatives**
**Groundwater Remedial Action Work Plan, Final**
**Garfield Avenue Group Sites, PPG, Jersey City, New Jersey**

| Alternative | Comparative Criteria [1] | | | | | | | Total Score | Application of the Remedial Technology |
|---|---|---|---|---|---|---|---|---|---|
| | Overall Protection of Human Health and the Environment | Achievement of Remedial Goals and Objectives | Long-Term Effectiveness and Permanence | Short-Term Effectiveness (Compatibility with Redevelopment) | Implementability | Comparative Cost (Low/Medium/High) | Regulatory Acceptance | | |
| **Alternative 4 Score** | 1 | 2 | 3 | 5 | 2 | 5 | 3 | | |
| Alternative 5: ISAB | - Groundwater is not currently used, nor expected to be used in the future, as potable water; the area is served by municipal water supply system.<br>- Three CEAs will provide notice to future receptors that groundwater is not suitable for potable water.<br>- Groundwater ECs are in place to prevent groundwater from impacting soil remediation areas. | - Comprehensive and permanent contaminant reduction.<br>- Eliminates mass flux leaving the site boundary. | - ISAB is effective and permanent as demonstrated by reduced hexavalent chromium ($Cr^{+6}$) concentrations in groundwater during the Phase I Interim Remedial Measure (IRM) performance monitoring period.<br>- Once reagent injections are completed, residual reductive capacity in the aquifer will continue to treat COCs. | - Short-term temporary infrastructure required.<br>- Can be integrated with redevelopment. | - Implementable<br>- Effectiveness has been demonstrated by a successful pilot test and ongoing performance monitoring for IRM Phases I and II.<br>- If alternative is constructed on properties not owned by PPG, access agreements will be necessary. | Medium | - Already accepted for IRM Phase I and II.<br>- Permanence of the remediation will be monitored. | 14 | ISAB is an effective source zone remedy, as demonstrated in the IRM Phase I and II as well as past pilot testing. |
| **Alternative 5 Score** | 1 | 2 | 2 | 3 | 2 | 3 | 1 | | |
| Alternative 6: ISCR with Calcium Polysulfide (CaSx) | - Groundwater is not currently used, nor expected to be used in the future, as potable water; the area is served by municipal water supply system.<br>- Three CEAs will provide notice to future receptors that groundwater is not suitable for potable water.<br>- Groundwater ECs are in place to prevent groundwater from impacting soil remediation areas. | - Comprehensive and permanent contaminant reduction.<br>- Eliminates mass flux leaving the site boundary. | - ISCR with CaSx is effective and permanent as demonstrated by reduced $Cr^{+6}$ concentrations in groundwater and an established reducing environment in the subsurface, which persisted through the end of the monitoring period (one year) in a successful pilot test (Table 3-3).<br>- Moderate-term monitoring | - Short-term temporary infrastructure required.<br>- Can be integrated with redevelopment. | - Implementable<br>- Effectiveness has been demonstrated by a successful pilot test and ongoing performance monitoring for IRM Phase II.<br>- If alternative is constructed on properties not owned by PPG, access agreements will be necessary. | Medium-High | - Already accepted for IRM Phase I and II.<br>- Permanence of the remediation will be monitored. | 15 | ISCR with CaSx is an effective source zone remedy, as demonstrated in past pilot testing. |
| **Alternative 6 Score** | 1 | 2 | 2 | 3 | 2 | 4 | 1 | | |
| Alternative 7: ISCR with FerroBlack®-H | - Groundwater is not currently used, nor expected to be used in the future, as potable water; the area is served by municipal water supply system.<br>- Three CEAs will provide notice to future receptors that groundwater is not suitable for potable water.<br>- Groundwater ECs are in place to prevent groundwater from impacting soil remediation areas. | - Comprehensive and permanent contaminant reduction.<br>- Eliminates mass flux leaving the site boundary. | - ISCR with FerroBlack®-H is effective and permanent as demonstrated by reduced $Cr^{+6}$ concentrations in groundwater and an established reducing environment in the subsurface, which persisted through the end of the monitoring period (one year) in a successful pilot test (Table 3-3). Long-term effectiveness has also been demonstrated through use of this reagent as a backfill amendment during soil remediation.<br>- Moderate-term monitoring | - Can be integrated with redevelopment. | - Implementable, as demonstrated by a successful pilot test.<br>- If alternative is constructed on properties not owned by PPG, access agreements will be necessary. | Medium | - Likely acceptable.<br>- Permanence of the remediation will be monitored. | 15 | ISCR with FerroBlack®-H is recommended as a source zone treatment technology, either as a standalone option, or in combination with a pump and treat remedy for site-wide coverage. |
| **Alternative 7 Score** | 1 | 2 | 2 | 3 | 2 | 3 | 2 | | |
| Alternative 8: Hydraulic Fracturing for ISCR | - Groundwater is not currently used, nor expected to be used in the future, as potable water; the area is served by municipal water supply system.<br>- Three CEAs will provide notice to future receptors that groundwater is not suitable for potable water.<br>- Groundwater ECs are in place to prevent groundwater from impacting soil remediation areas. | - Facilitates reagent placement in low permeability units.<br>- Fracturing is a delivery method, therefore this remedy must be combined with ISAB or ISCR to achieve remedial goal and objectives. | -There is limited data on the success of hydraulic fracturing for treatment of mass in low permeability units. Successful implementation of hydraulic fracturing may vary based on heterogeneities and in-situ stresses of the formation. | - Short-term temporary infrastructure required.<br>- Can be integrated with redevelopment. | - Successful implementation of hydraulic fracturing may vary based on heterogeneities and in-situ stresses of the formation. The pilot test demonstrated that it could be used to emplace reagent in the low permeability unit, but success will vary across the Project Area.<br>- If alternative is constructed on properties not owned by PPG, access agreements will be necessary. | High | - Challenging.<br>- Effectiveness and permanence of the remediation will be monitored. | 26 | Hydraulic fracturing is not recommended. Heterogeneities in the formation make this technology technically impracticable. |
| **Alternative 8 Score** | 1 | 5 | 4 | 3 | 4 | 5 | 4 | | |
| Alternative 9: Enhanced Attenuation | - Groundwater is not currently used, nor expected to be used in the future, as potable water; the area is served by municipal water supply system.<br>- Three CEAs will provide notice to future receptors that groundwater is not suitable for potable water.<br>- Groundwater ECs are in place to prevent groundwater from impacting soil remediation areas. | - Once reagent injections (chemical or biological) are completed, residual reductive capacity in the aquifer will continue to treat COCs.<br>- Continues active treatment after in-situ injections are complete. | - Once reagent injections (chemical or biological) are completed, residual reductive capacity in the aquifer will continue to treat COCs for an estimated 8-10 years. | - No additional infrastructure is required after ISAB or ISCR is complete.<br>- Can be integrated with redevelopment. | - Implementable as demonstrated by successful ISAB and ISCR pilot tests and subsequent performance monitoring.<br>- If components of alternative (e.g., monitoring wells) are constructed on properties not owned by PPG, access agreements will be necessary. | Low (no additional cost after ISCR or ISAB) | - Likely acceptable with ISCR or ISAB.<br>- Permanence of the remediation will be monitored. | 10 | Enhanced attenuation is an effective remedy after the successful implementation of ISAB or ISCR. Alternative relies on the residual reductive capacity of the aquifer to continue to treat COCs. |

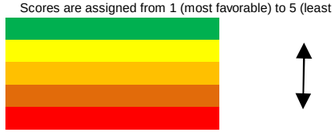
**Table 5-1**
**Comparative Analysis of Groundwater Remedial Alternatives**
**Groundwater Remedial Action Work Plan, Final**
**Garfield Avenue Group Sites, PPG, Jersey City, New Jersey**

| Alternative | Comparative Criteria [1] | | | | | | | Total Score | Application of the Remedial Technology |
|---|---|---|---|---|---|---|---|---|---|
| | Overall Protection of Human Health and the Environment | Achievement of Remedial Goals and Objectives | Long-Term Effectiveness and Permanence | Short-Term Effectiveness (Compatibility with Redevelopment) | Implementability | Comparative Cost (Low/Medium/High) | Regulatory Acceptance | | |
| **Alternative 9 Score** | 1 | 2 | 2 | 1 | 1 | 1 | 2 | | |
| **Monitored Natural Attenuation** | | | | | | | | | |
| Alternative 10: Monitored Natural Attenuation only | - Groundwater is not currently used, nor expected to be used in the future, as potable water; the area is served by municipal water supply system.<br>- Three CEAs will provide notice to future receptors that groundwater is not suitable for potable water.<br>- Groundwater ECs are in place to prevent groundwater from impacting soil remediation areas. | - Once active remedy (i.e., reagent injections (chemical or biological) followed by enhanced attenuation) are completed, natural mechanisms will continue to treat COCs to meet NJDEP GWQS. | - Once active remedy (i.e., ISAB or ISCR, followed by enhanced attenuation) is completed, natural mechanisms will continue to treat COCs to meet NJDEP GWQS in the long term. | - Least amount of infrastructure required.<br>- Can be integrated with redevelopment. | - Implementable, only monitoring is required.<br>- If components of alternative (e.g., monitoring wells) are constructed on properties not owned by PPG, access agreements will be necessary | Low | - Likely acceptable after active remedy implemented.<br>- Need to prove plume is stable and exposure risk is mitigated through robust monitoring program.<br>- Permanence of the remediation will be monitored.<br>- Need to accept a long cleanup timeframe. | 13 | MNA is a proven effective alternative to achieve the remedial goal and objectives. |
| **Alternative 10 Score** | 1 | 2 | 2 | 1 | 1 | 1 | 5 | | |

Notes

1. Comparative criteria ranking system is described below.

Scores are assigned from 1 (most favorable) to 5 (least favorable). The lowest overall score is most favorable.



| | |
|---|---|
| Most favorable | 1 |
| | 2 |
| | 3 |
| | 4 |
| Least favorable | 5 |

Acronyms:

CaSx: calcium polysulfide
CEA: Classification Exception Area
COC: contaminant of concern
$Cr^{+6}$: hexavalent chromium
EC: engineering control
GWQS: Groundwater Quality Standards
GWTP: groundwater treatment plant
IRM: Interim Remedial Measure
ISAB: in-situ anaerobic bioprecipitation
ISCR: in-situ chemical reduction
MNA: monitored natural attenuation
NJDEP: New Jersey Department of Environmental Protection
PRB: permeable reactive barrier

**Table 5-2. Groundwater Remediation Strategy Summary**
Groundwater Remedial Action Work Plan, Final
Garfield Avenue Group Sites
PPG, Jersey City, NJ

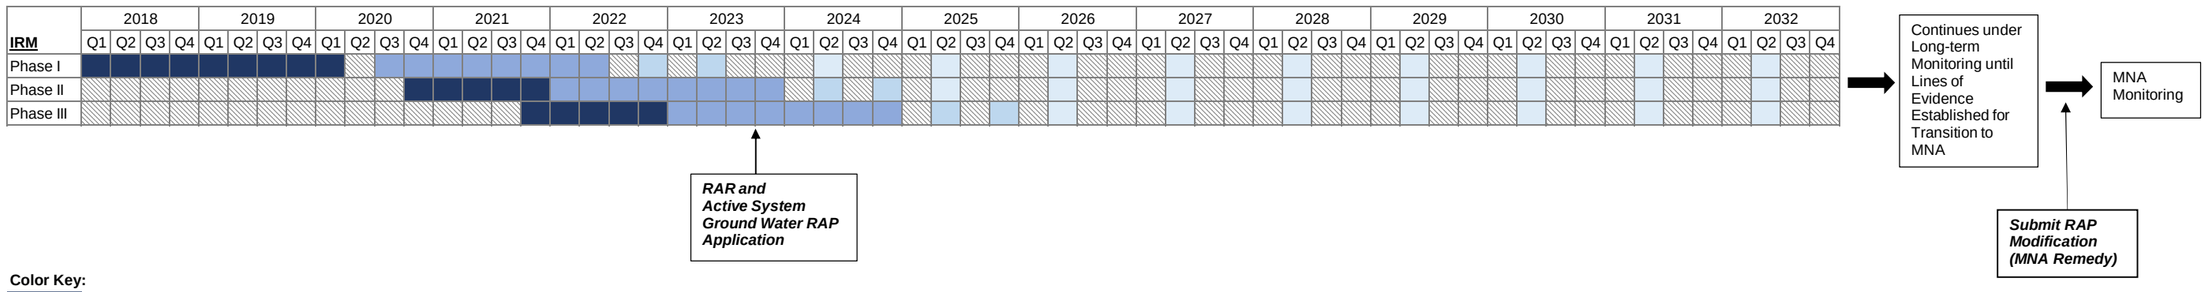
| Deep | ISAB and/or ISCR<br>(IRM Phases I and II)<br><br>ISAB and/or ISCR<br>(IRM Phase III)<br><br>FerroBlack®-H Emplacement<br>(IRM Phase III)[6] | | | | Sheet Pile (where present)<br>Classification Exception Area<br>Long-term Groundwater Monitoring |
| Bedrock[7] | N/A | | MNA | Technical Impracticability Determination | Classification Exception Area<br>Long-Term Groundwater Monitoring |

**Notes:**
[1] = Refer to Figure 3-2 for the horizontal extents of each IRM phase in each water-bearing zone.
[2] = Once ISAB and/or ISCR injections and associated performance monitoring are completed via in-situ active treatment, residual abiotic or reductive capacity in the aquifer will continue to treat COCs under an enhanced attenuation active remedy. The duration of the enhanced attenuation and associated long-term monitoring may be shortened if lines of evidence point to a transition to MNA sooner than the estimated timeframe presented on this table.
[3] = MNA remedy will continue as necessary to reach the groundwater quality standards, thus groundwater institutional and engineering controls will be monitored and maintained during this time period.
[4]= Both during and after active treatment (Parts 1, 2 or 3 of the active treatment remedy as depicted on Figure 5-1), should the lines of evidence indicate that the GWQS for the COCs cannot be achieved in certain areas via the selected active groundwater remedies, either due to the presence of low permeability zones, technology limitations, or limitations with reagent (e.g., molasses, EVO, CaSx, FerroBlack®-H) distribution or groundwater extraction, contingency remedies, such as localized/targeted treatment using ISAB or ISCR, or FerroBlack®-H emplacement will be implemented in applicable areas.
[5] = Estimated timeframe provided; timing will be guided by monitoring data and may be shorter or longer, as appropriate
[6] = FerroBlack®-H emplacement will provide in-situ treatment for targeted areas within the lower portion of the deep water-bearing zone on Site 114.
[7] = Additional groundwater remedial investigation is necessary in the bedrock water-bearing zone in the southwest corner of Site 114 to complete delineation of $Cr^{+6}$ and Cr impacts, thus a final remedial decision for the bedrock water-bearing zone will be determined upon completion of the RI.

**Acronyms:**
CaSx = calcium polysulfide; COC = contaminant of concern; Cr = chromium (total); $Cr^{+6}$ = chromium (hexavalent); EVO = emulsified vegetable oil; GWQS = Groundwater Quality Standard; IRM = Interim Remedial Measure; ISAB = in-situ anaerobic bioprecipitation; ISCR = in-situ chemical reduction; MNA = monitored natural attenuation; N/A = not applicable; NJDEP = New Jersey Department of Environmental Protection; RAP-GW = Remedial Action Permit - Groundwater; TBD = to be determined;
µg/L = micrograms per liter

**Table 7-2. Groundwater Monitoring Plan for Active Remedy**
Groundwater Remedial Action Work Plan, Final
Garfield Avenue Group Sites
PPG, Jersey City, New Jersey



**Color Key:**

- Treatment monitoring (monthly) (Part 1 of active treatment remedy as depicted on Figure 5-1)
- Post-treatment performance monitoring (quarterly) (Part 1 of active treatment remedy as depicted on Figure 5-1)
- Monitoring of enhanced attenuation* (semi-annual) (Part 2 of active treatment remedy as depicted on Figure 5-1)
- Monitoring of enhanced attenuation* (annual) (Part 2 of active treatment remedy as depicted on Figure 5-1)

**Notes:**

1. Analysis for the treatment and post-treatment performance monitoring will be in accordance with the PBR authorizations for each IRM phase.
2. For the post-PBR monitoring program, samples will be analyzed for: $Cr^{+6}$, and CCPW metals. During the Phase III IRM program, groundwater samples collected from Site 199 will also be analyzed for PCE and its breakdown products (i.e., TCE, cis-1,2-dichloroethene and vinyl chloride).
3. Key geochemical indicators (e.g., sulfates, sulfides, iron, total organic carbon, etc.) and field parameters (pH, ORP, dissolved oxygen, specific conductivity, temperature, and turbidity) will be collected during all sampling events.

* - enhanced attenuation refers to the phase of continued decrease of contaminant concentrations (Cr and $Cr^{+6}$) through natural processes following active treatment (AECOM, 2016).

$Cr^{+6}$ = hexavalent chromium
CCPW = Chromate Chemical Production Waste
CCPW metals = antimony, chromium, nickel, thallium, and vanadium
IRM = interim remedial measures
MNA = monitored natural attenuation
ORP = oxidation-reduction potential
PBR = permit-by-rule
PCE = tetrachloroethylene
RAP = remedial action permit
RAR = remedial action report
TCE = trichloroethylene

2013 to 2021

## Active Treatment

### Part 1 of Active Treatment Remedy – 2017 to 2024
### Phase I, II and III Interim Remedial Measures (IRMs)
### (per NJDEP Permit-by-Rule [PBR] Authorizations)

- Targets in-situ treatment of treatable zones of $Cr^{+6}$ within the Cr 1,000 ppb isopleth
- In-situ Anaerobic Biodegradation (ISAB) and In-situ Chemical Reduction (ISCR) via Phase I, II and III IRMs
- Robust Area-Wide Groundwater Monitoring and Reporting per PBRs

2017 to 2023

Submit Remedial Action Report
and submit request for Active Category Remedial Action Permit, including
Area-wide Monitoring Network for Parts 2 and 3 of Active Remedy

2023

- Robust Area-Wide Groundwater Monitoring and Reporting per PBRs (continues)
- Closeout of PBRs

2024

Remedial Action Report approval
Active Category Remedial Action Permit issued

### Part 2 of Active Treatment Remedy – 2024 to (estimated) 2032*
### Enhanced Attenuation (i.e., post-PBR period)

2024 to 2032

- Continued In-situ Treatment via ISAB/ISCR induced by the IRMs – "Enhanced Attenuation"
- Groundwater monitoring to demonstrate ISAB and ISCR ongoing
- Reporting as per NJDEP Guidance
- At completion of ISAB and ISCR treatment, transition to long-term groundwater monitoring

### Part 3 of Active Treatment Remedy – (estimated) 2032* to (estimated) TBD*
### Long-Term Groundwater Monitoring

2032 to TBD

- Long term groundwater monitoring and reporting per NJDEP guidance
- Remedy continues under Active Category Remedial Action Permit until transition to Monitored Natural Attenuation Category Remedial Action Permit is suitable

## Monitored Natural Attenuation Treatment

- Continue long term groundwater monitoring and reporting per NJDEP guidance under Monitored Natural Attenuation Remedial Action Permit

TBD to 2062

* *Estimated timeframe provided; timing will be guided by monitoring data and may be shorter or longer, as appropriate*

| Date | July 15, 2021 | | |

On behalf of PPG, AECOM is hereby providing a response to New Jersey Department of Environmental Protection (NJDEP) and Jersey City comments on the March 24, 2021 *Revised Draft Groundwater Remedial Investigation (RI) Report, PPG Garfield Avenue Group, Hudson County Chromium Sites, Jersey City, New Jersey* (GW-077) and the March 31, 2021 *Draft Groundwater Remedial Action Work Plan (RAWP), PPG Garfield Avenue Group, Hudson County Chromium Sites, Jersey City, New Jersey* (GW-008) regarding the definition of low permeability at the Garfield Avenue Group Sites (the Project Area). Although extensive discussions have been held with NJDEP and the Technical Consultant regarding this topic, NJDEP continues to request additional information and discussion; thus, PPG has prepared this separate response focusing on this topic.

## Introduction

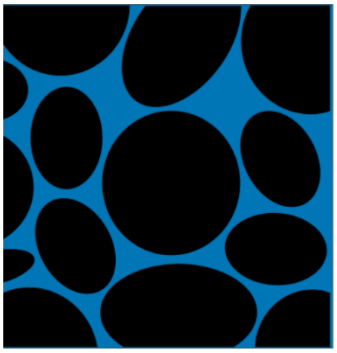
The terms porosity and permeability and their relationship to hydraulic conductivity are described herein. Within the context of this discussion, it is important to understand that there is no single value of hydraulic conductivity that can be used to describe a material as having high or low permeability. No "bright line" exists in nature, rather, values of hydraulic conductivity for subsurface materials range over several orders of magnitude. The subsurface materials (overburden) at the Project Area do not consist of homogenous soils that exhibit a single permeability (e.g., a 50-foot lens of beach sand), in which case, stakeholder agreement on low permeability would be easy. Instead, the soils in the Project Area are highly heterogeneous because the overburden at the Project Area was formed by glaciers, which resulted in the deposition of a multi-layered sequence containing a complex mixture of soil types. In such an environment, no single value of hydraulic conductivity can be established to denote a soil type

as having high or low permeability. Further, there is no one field test that is 100% accurate in measuring hydraulic conductivity. Instead, a comprehensive review of existing site information that integrates available hydraulic conductivity data, real-time geologic logging, and observations of flow rates and reagent distribution during the Interim Remedial Measures (IRMs) is necessary to evaluate soil permeability and understand whether or not remediation reagents can be effectively delivered to a targeted soil type. This assessment has been completed at the Project Area via implementation of the Phase I and Phase II IRMs, where over 12 million gallons of remediation reagents have been injected into the overburden. Information gathered during these IRMs has shown that they are successful at delivering remediation reagents to sands, gravels, silty sands, and sandy silts within portions of the intermediate and deep water-bearing zones, as supported by the significant concentration reductions of $Cr^{+6}$ compared to baseline levels, in some cases up to four orders of magnitude. Furthermore, lessons learned from the IRMs include the understanding that delivery of remediation reagents to silts and clays is difficult.

## Definitions of Porosity, Permeability, and Hydraulic Conductivity

Porosity is the amount of empty space within a given material. In a soil or rock, the porosity (empty space) exists between the grains of minerals. In a material like gravel, the grains are large and there are lots of empty spaces between them because they do not fit together very well (see Figure 1). However, in a material that is a mixture of gravel, sand, and clay, the porosity is much less because the smaller grains fill the spaces (see Figure 2). The amount of water a material can hold is directly related to the porosity because water will fill the empty spaces in a material. Porosity is measured by the percentage of empty space that exists within a particular porous media.

Figure 1



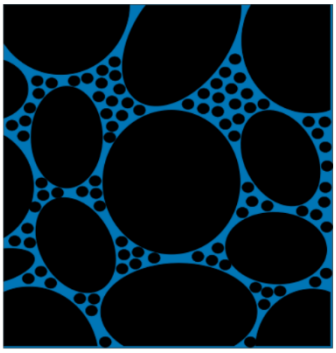


Figure 2

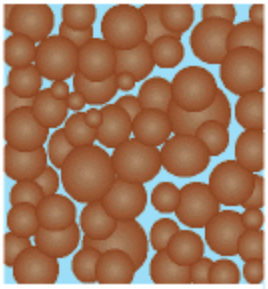
Permeability is closely related to porosity. Permeability refers to how connected pore spaces are to one another. If a material has high permeability, then pore spaces are connected to one another and allow water to flow from one space to another. Referring to Figure 1, it is easy to visualize how water would readily flow within the pore spaces around the grains of gravel. However, if there is low permeability, then the pore spaces are isolated (see Figures 2, 3 and 4). In a low-permeability material, most of the pore spaces are blocked, meaning water cannot flow through it easily – rather, water will flow where the pore spaces are connected (see Figure 4 -- the dark blue coloring represents water flowing through this low permeability material). As shown in Figure 4, water will not flow to, or through, some pore spaces (shaded in light blue) due to the low permeability of the material.

Figure 3



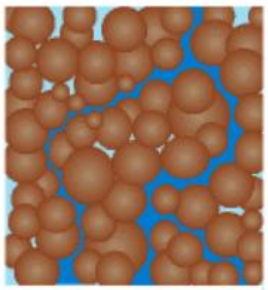


Figure 4

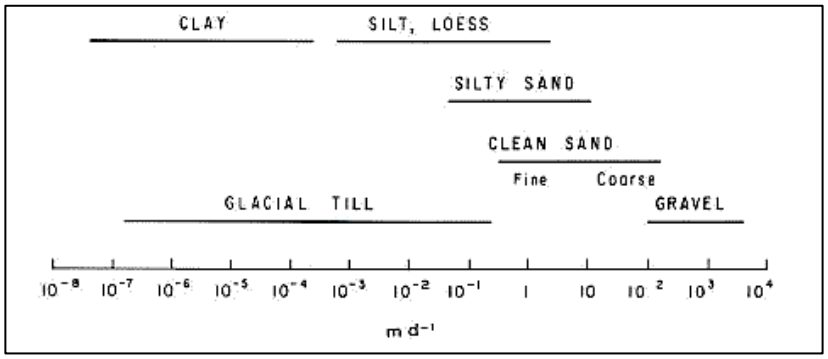
Hydraulic conductivity is a measurement of the ease with which a fluid (usually water) can move through connected pore spaces or fractures. Its magnitude depends on how well connected the pore spaces of the material are (i.e., how permeable the material is). Materials with high permeability have a high hydraulic conductivity, whereas low-permeability materials have low hydraulic conductivity. Values of hydraulic conductivity for subsurface materials range over several orders of magnitude, and the permeability of a single soil type is relative to its surrounding soil types. For example, a lens of fine sand within a sequence of coarse gravel exhibits low permeability relative to the surrounding gravel, whereas a lens of fine sand within a sequence of silt and clay exhibits high permeability relative to the surrounding silts and clays.

## Definition of Low Permeability for Soils at the Project Area

The definition of low permeability as it relates to groundwater flow is well documented in the literature and is a fundamental concept taught in introductory hydrogeology courses (Fetter, 2001). Low-permeability geologic materials are commonly understood to include soils that are dominated by silt or clay, or soils that are described as clayey or silty glacial till (see Figure 5).

Figure 5



| Formation | Hydraulic Conductivity, m/day |
|---|---|
| Unconsolidated Formations | |
| Gravel, coarse | 1000–8600 |
| Gravel, medium | 20–1000 |
| Gravel, fine | 20–50 |
| Sand, coarse | 0.1–500 |
| Sand, medium | 0.1–50 |
| Sand, fine | 0.01–20 |
| Silt, sandy | 1–4 |
| Silt, clayey | 0.2–1 |
| Till, gavel | 30 |
| Till, sandy | 0.2 |
| Till, clayey | $\leq 10^{-5}$ |
| Clay | ≤ 0.0005 |

This is important for the Project Area, because visual evidence of the presence of silts, clays, or glacial till (i.e., low permeability soils) is readily available from the 30,000 feet of soil borings completed at over 850 locations within the 49-acre Project Area during investigation activities. For each soil boring, a log is developed as required by NJDEP *Ground Water Technical Guidance for Site Investigation, Remedial Investigation and Remedial Action Performance Monitoring* and the observed soils are described using the Unified Soil Classification System (USCS) (Howard, 1986). The USCS is used universally to describe soils and is accepted by the NJDEP. Within the Project Area, boring logs identify low-permeability soils using the USCS codes listed below.

ML: Inorganic silts and very fine sands, rock flour, silty of clayey fine sands or clayey silts with slight plasticity.

CL: Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays.

OL: Organic silts and organic silty clays of low plasticity.

MH: Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts.

CH: Inorganic clays of high plasticity, fat clays.

OH: Organic clays of medium to high plasticity, organic silts

PT: Peat and other highly organic soils.

The Project Area soils outlined above have also been characterized by over 2,700 vertical feet of hydraulic profile tool (HPT) borings, which provide high resolution insights into the hydraulic conductivity of these materials and support the conclusion that these are low-permeability soils (see Figure 6 for an example of a HPT log identifying low and high permeability intervals within overburden soils). HPT logs are generated by advancing a probe through the subsurface at a constant rate while water is injected through a screen on the side of the probe. There is a pressure sensor on the probe that measures how easily the water was able to enter the soil. The pressure response measures the relative ability (compared to other surrounding soils) of the soil to transmit water. The use of HPT data to assess low permeability at the Project Area was reviewed with the NJDEP and the Technical Consultant in a virtual meeting held on February 16, 2021. A copy of the presentation provided at this meeting is attached for reference.

In addition to the above listed soil materials, the basal till in the Project Area consists of silty clays, sandy silts, and silty sands with subrounded to subangular fine to coarse gravel and cobbles and occasional interbedded lenses of clay, silt, or fine sand. Therefore, Project Area soils described by the USCS codes above or designated as “basal till” are considered low-permeability soils.

## In-situ Active Treatment in Project Area

The *in-situ* remedies selected for active groundwater remediation within the Project Area include the delivery of remediation reagents to saturated soils to establish groundwater conditions that are favorable for the reduction of hexavalent chromium ($Cr^{+6}$) to trivalent chromium ($Cr^{+3}$). Three phases of IRMs deliver remediation reagents to geologic materials within portions of the intermediate and deep water-bearing zones where $Cr^{+6}$ is present.

The IRMs do not target the basal till because remediation reagents cannot be delivered to all available pore spaces within this low-permeability soil horizon (refer to Figure 4 – it would not be possible to deliver reagents to all available pore spaces – the light blue spaces would be by-passed). Thus, we say that remediation reagents cannot be easily delivered through the pore spaces within low permeability soil horizons. This is supported by the technical paper *Groundwater Remediation in Low-Permeability Settings: The Evolving Spectrum of Proven and Potential* by Horst and Schnobrich, et al. (2019) which provides a practical definition of low-permeability as being soils "*where it is very challenging to get fluids either in or out*."

Lenses of low-permeability materials exist within the intermediate and deep water-bearing zones (see Figure 6), as a result, the IRM remediation wells were installed across intervals of both higher and lower permeability materials with the understanding that remediation reagents would be variably distributed through each soil type. In these cases, it can be expected that $Cr^{+6}$ will be treated in the permeable lenses and that residual concentrations of $Cr^{+6}$ will remain in the low-permeability lenses even after completion of the IRMs, because remediation reagents cannot be delivered to all pore spaces within the low-permeability materials.

The IRMs address the expected short-term, localized increase in $Cr^{+6}$ concentrations that may occur for a limited period after the IRM injections cease. These increases result from "back-diffusion" of $Cr^{+6}$ into surrounding higher permeability soils from low-permeability soils into which remediation reagents could not be injected. The release of $Cr^{+6}$ from such low-permeability soils will be highest within the first several years following completion of IRM treatment, after which the rate of $Cr^{+6}$ diffusion will decline significantly during post-treatment. The excess remediation reagents being delivered by the IRMs to the more permeable intervals of the intermediate and deep water-bearing zones surrounding low-permeability soils are expected to persist in the subsurface during this back-diffusion period. Therefore, when there is back-diffusion of $Cr^{+6}$ into already treated areas, the excess volume of remediation reagents will continue to induce geochemical conditions that are favorable to the treatment of $Cr^{+6}$.

## Long-Term Monitoring and Management

The Groundwater Remedial Action Work Plan for the Project Area includes completion of the IRMs to provide short-term $Cr^{+6}$ reduction and establish a sustained reactive zone to continue $Cr^{+6}$ treatment following IRM completion, installation of reactive barriers in the lower portion of the deep water-bearing zone, long-term groundwater monitoring to track continued $Cr^{+6}$ natural attenuation, groundwater engineering controls (such as FerroBlack®-H amended fill and sheet pile), and establishment of a NJDEP Classification Exception Area.

It is important to note that despite the decades that have elapsed since the former source areas were removed, the total chromium (Cr) groundwater plume in the Project Area does not extend very far from the former source areas, even where preferential pathways exist, such as utilities or other anthropogenic features. The IRMs target delivery of remediation compounds to permeable soils within portions of the intermediate and deep water-bearing zones where $Cr^{+6}$ is present – and by targeting these permeable zones, we are targeting remediation of the most prevalent pathway for Cr to migrate away from the Project Area.

## Summary

Permeability refers to how connected pore spaces are to one another. If the material has high permeability, then pore spaces are connected to one another and allow water to flow from one space to another. At remediation sites, these spaces provide the conduits for contaminants to migrate, for plumes to expand, and drive potential future risk. If the material has low permeability, then the pore spaces are isolated and blocked, indicating that water cannot flow through it easily. Contaminants present in these soils are not readily mobile and do not represent a significant risk if the areas can be managed by other naturally occurring processes or via institutional means. In the Project Area, there is visual evidence of the presence of silts, clays, and glacial till from the thousands of feet of soil borings completed. As shown on Figure 5, there is no singular hydraulic conductivity value that can be assigned to these materials; no such "bright line" exists in nature. Therefore, for practical purposes at the Project Area within the context of groundwater remediation, any soils described by USCS codes ML, CL, OL, MH, CH, OH and PT, or as basal till, are considered to be low-permeability soils.

The IRMs target delivery of remediation reagents to permeable soils within portions of the intermediate and deep water-bearing zones where $Cr^{+6}$ is present – and by targeting these permeable zones, PPG is targeting remediation of the most prevalent pathway for Cr to migrate away from the Project Area. The IRMs do not target the basal till because remediation reagents cannot be easily delivered to all available pore spaces within this low-permeability soil horizon (refer to Figure 4). In areas of low-permeability, where remediation reagents cannot be delivered into the pore spaces of the targeted materials, residual Cr will be managed via the excess volume of remediation reagents delivered to the surrounding high-permeability soils during the IRMs, and via natural attenuation and long-term monitoring.

LOWER PERMEABILITY TECHNICAL BREAKOUT

# LOWER PERMEABILITY TECHNICAL BREAKOUT

PPG Site 114

February 16, 2021

# Remedy Development Framework

- Based on initial CSM, the 2010 *Remediation Strategy for CCPW in Groundwater* acknowledged that complete treatment was infeasible
  - Implement groundwater treatment for bulk removal prior to transition to MNA
  - Target Cr(VI) goal of 1,000 µg/L
- Evolution of CSM has provided better insights into what is feasible
- Remedy development framework considering the following elements:
  - Permeable vs impermeable soils?
  - If soils are permeable, is the Cr(VI) mass significant in concentration and magnitude?
  - As appropriate, select combination of active and passive groundwater remedies to achieve bulk removal and leverage MNA and site controls

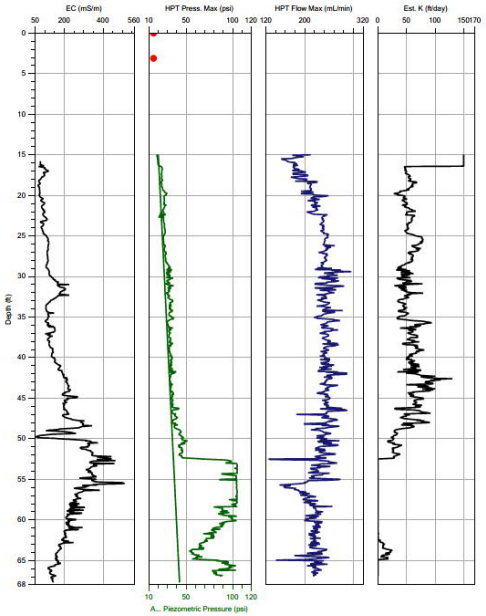
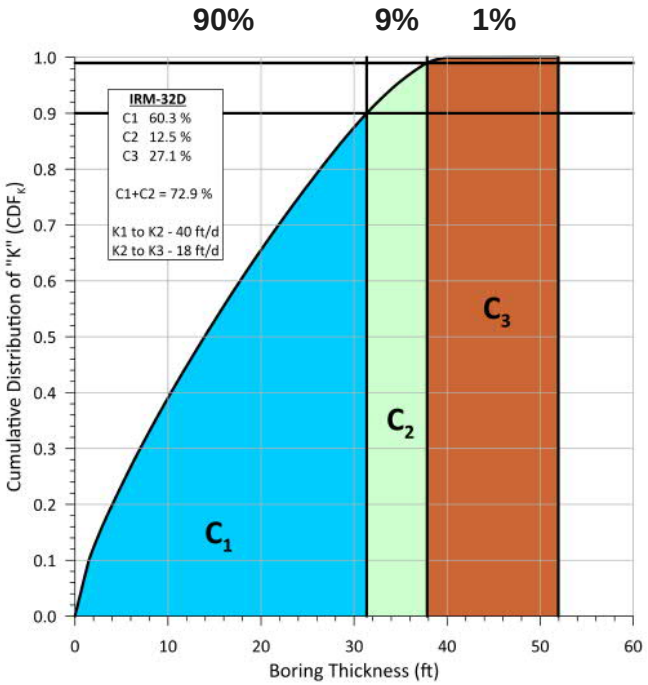
# Sorting K Distribution

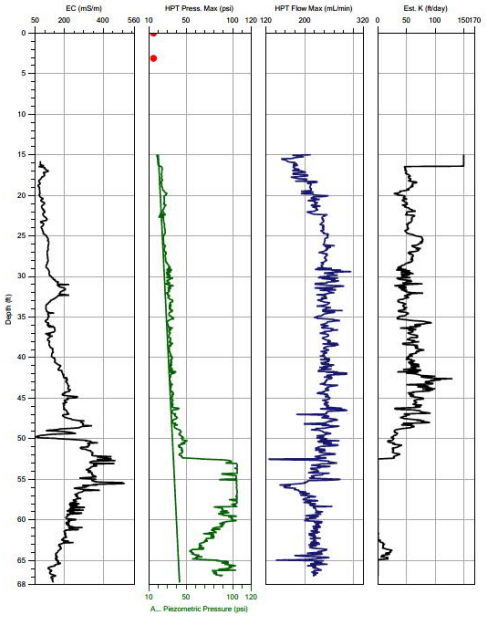


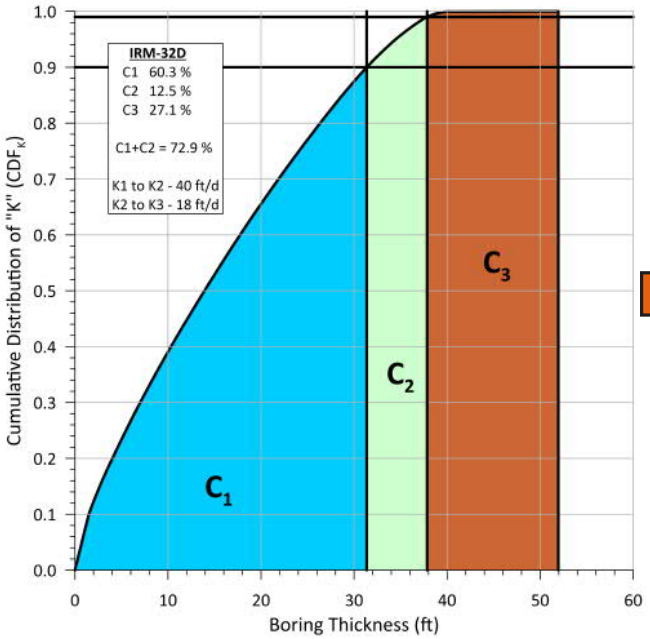


- CDF plots sort boring K data based on relative permeability
- Zones separated based on order of magnitude differences in relative flow (90%, 9% and 1%)
- Transition points are unique to each boring, but are still representative of groundwater flow through aquifer soils
- From Phase II IRM data, average K value for C2-C3 transition was 11 ft/day or $3.74 \times 10^{-3}$ cm/sec

© Arcadis 2015

# Understanding K Distribution





**Sorting of all HPT K data indicates:**

- 54.6% in C1 – permeable zone
- 19.7% in C2 – limited permeability
- 25.8% in C3 – low permeability

**Key question: If ~75% is treatable, what happens to the remaining 25%?**

© Arcadis 2015

# Low Permeability Findings

- Site 114 heterogeneity and permeability contrasts have significant bearing on what can be implemented within the aquifer
- Soils dominated by silts and clays, or as “tight” and “dense” are going to be inaccessible to remediation – while often logged as “wet”
- Using HPT output data, inaccessible soils are generally 3 ft/day ($1x10^{-3}$ cm/sec) or lower
- Higher permeability zones must be connected to be treatable, and relevant from a transport and risk perspective

© Arcadis 2015

## SECTION A. SITE NAME AND LOCATION

Site Name: Garfield Avenue Site 114 and Former Halladay Street Gas Works

AKAs:

Street Address: 900 Garfield Avenue

Municipality: Jersey City (*Township, Borough or City*)

County: Hudson Zip Code: 07305

Program Interest (PI) Number(s): G000008791

Case Tracking Number(s) for this submission:

Municipal block(s) and lot(s) where the **proposed discharge(s)** would occur:

Block # 21501 Lot #(s) 16,17,18, 19, 20 Block # Lot #(s)

Block # Lot #(s) Block # Lot #(s)

## SECTION B. FEE AND DISCHARGE INFORMATION

DGW Proposal Review Fee ..... $350.00

**Discharge Type** *(check all that apply)*

☒ Discharge of Recovered Ground Water

Will the discharge be a result of dewatering only? ..... ☒ Yes ☐ No

☒ Discharge that is part of an *In situ* Remediation

☐ Discharges other than those above *(see instructions for more information)*

**Facility Type** *(check all that apply)*

☒ Underground Injection Control (UIC) facility (i.e., any type of injection)

☐ Non-UIC (e.g., surface application) *(see instructions for more information)*

**Attach a Discharge to Ground Water Proposal to this form** *(see instructions)* See attached CD

## SECTION C. PUBLIC NOTICE PROVISIONS *(Does not apply to residential heating oil tank cases)*

Is the proposed discharge lasting greater than 180 days? ..... ☒ Yes ☐ No

If "Yes," attach a copy of the public notice written as you intend it to be published. *(see instructions)* See attached CD, Appendix A

## SECTION D. SITE USE AND GROUND WATER CLASSIFICATION

**Current Site Use** *(check all that apply)*

☐ Industrial ☐ Agricultural
☐ Residential ☐ Park or recreational use
☐ Commercial ☒ Vacant
☐ School or child care ☐ Government
☐ Other

**Intended Future Site Use** *(check all that apply)*

☐ Industrial ☐ Park or recreational use
☐ Residential ☐ Vacant
☐ Commercial ☐ Government
☐ School or child care ☒ Future site use unknown

What is the ground water classification for this site as per N.J.A.C. 7:9C? *(check all that apply)*

☐ Class I-A ☒ Class II-A
☐ Class I-PL Pinelands Protection Area ☐ Class III-A
☐ Class I-PL Pinelands Preservation Area ☐ Class III-B

## SECTION E. RECEPTOR EVALUATION SUMMARY

### Non-UHOT Cases

1. Have any of the following been identified on the site or within 200 feet of the site boundary?

   Check all that apply.

   ☒ Residences
   ☐ Child care facilities
   ☐ Public and private schools (K-12)
   ☐ Surface water
   ☒ Other occupied buildings
   ☒ Public parks and playgrounds

2. Did the well search conducted as a part of the receptor evaluation show any well use (potable, industrial, or irrigation)? ☐ Yes ☒ No

   If "Yes," indicate the type of use and approximate distance (closest occurrence) from site: *(Check all that apply)*

   ☐ Potable Distance from site: _____ feet

   ☐ Industrial Distance from site: _____ feet

   ☐ Irrigation Distance from site: _____ feet

3. Have any of these receptors been impacted? ☐ Yes ☒ No
   If "Yes," Do you have an NJDEP assigned Case Manager? ☐ Yes ☐ No

   If "Yes," please list the Case Manager: _____

### UHOT Cases

1. Is ground water contamination above the Ground Water Remediation Standards? ☐ Yes ☐ No
   If "Yes," answer questions 2 and 3.
2. Has a potable well been identified within 100 feet of the contamination? ☐ Yes ☐ No
3. Have any potable wells been impacted? ☐ Yes ☐ No
   If "Yes," has the NJDEP been notified? ☐ Yes ☐ No

## SECTION F. PERSON RESPONSIBLE FOR CONDUCTING THE REMEDIATION INFORMATION AND CERTIFICATION

Full Legal Name of the Person Responsible for Conducting the Remediation: PPG Industries, Inc.

Representative First Name: Mark Representative Last Name: Terril

Title: Corporate Director Environmental Affairs

☐ Check this box if the person above is also the property owner of the site or their representative. If this person is not the site property owner, please ensure the site property owner's name and address is included in the DGW Proposal, and also indicate that the property owner has been informed about the proposed discharge.

**SECTION G. LICENSED SITE REMEDIATION PROFESSIONAL INFORMATION AND STATEMENT**

LSRP ID Number: _____

First Name: _____ Last Name: _____

Phone Number: _____ Ext: _____ Fax: _____

Mailing Address: _____

City/Town: _____ State: _____ Zip Code: _____

Email Address: _____

This statement shall be signed by the LSRP who is submitting this notification in accordance with N.J.S.A. 58:10C-14, and N.J.S.A. 58:10B-1.3b(1) and (2).

*I certify that I am a Licensed Site Remediation Professional authorized pursuant to N.J.S.A. 58:10C to conduct business in New Jersey. As the Licensed Site Remediation Professional of record for this remediation, I:*

**[SELECT ONE OR BOTH OF THE FOLLOWING AS APPLICABLE]:**

☐ *directly oversaw and supervised all of the referenced remediation, and\or*

☐ *personally reviewed and accepted all of the referenced remediation presented herein.*

*I believe that the information contained herein, and including all attached documents, is true, accurate and complete.*

*It is my independent professional judgment and opinion that the remediation conducted at this site, as reflected in this submission to the Department, conforms to, and is consistent with, the remediation requirements in N.J.S.A. 58:10C-14.*

*My conduct and decisions in this matter were made upon the exercise of reasonable care and diligence, and by applying the knowledge and skill ordinarily exercised by licensed site remediation professionals practicing in good standing, in accordance with N.J.S.A. 58:10C-16, in the State of New Jersey at the time I performed these professional services.*

*I am aware pursuant to N.J.S.A. 58:10C-17 that for purposely, knowingly or recklessly submitting false statement, representation or certification in any document or information submitted to the board or Department, etc., that there are significant civil, administrative and criminal penalties, including license revocation or suspension, fines and being punished by imprisonment for conviction of a crime of the third degree.*

# 1 INTRODUCTION AND IRM OVERVIEW

On behalf of PPG, Arcadis U.S., Inc. (Arcadis) prepared this *Groundwater Interim Remedial Measure (IRM): Phase I Design and Permit-By-Rule (PBR) Authorization Request* (Design) for the Garfield Avenue Group Sites located in Jersey City, New Jersey (the site, **Figure 1**).

In order to expedite the treatment of groundwater associated with the portion of the Garfield Avenue Group Sites impacted with total and hexavalent chromium (Cr and Cr[VI]), an IRM approach has been developed consistent with the December 2016 technical memorandum titled, *GW-050: Concepts for Groundwater Interim Remedial Measures for Garfield Avenue Group Sites, Jersey City, New Jersey* (AECOM 2016) and subsequent discussions with the New Jersey Department of Environmental Protection (NJDEP) on May 18, 2017 and May 31, 2017. The envisioned IRM Program will be implemented in phases, with each phase representing a manageable portion of the affected area. The phases will be implemented successively to test the technical approach and allow for continuous optimization of the process with the details of each phase beyond the first dependent on what is observed in the prior phase. The IRM Program will focus primarily on the intermediate and deep water-bearing zones where source removal has been completed and where elevated Cr(VI) is present in the groundwater. In the case of Phase I, however, the IRM Program will also include a small area containing Cr in the shallow water-bearing zone.

Phase I of the IRM, the subject of this Design and PBR Authorization Request, will be implemented at Site 114, which is located at 900 Garfield Avenue in Jersey City, New Jersey (**Figure 2**). The proposed design for Phase I, as described herein, has been configured as follows:

- Treatment will occur in both the northern and southern portions of Site 114.
- In the northern portion of Site 114, groundwater will be recovered from the areas of highest total Cr and Cr(VI) concentrations. This provides direct treatment of those areas by removing Cr, resulting in less overall Cr in the subsurface. The recovered water will be treated using the existing water treatment plant so that it is suitable for re-injection.
- The treated water will be amended with substrates to provide a degradable source of organic carbon. It will be amended prior to reinjection in the southern portion of Site 114, where concentrations of Cr are lower and more amenable to rapid bioremediation. The organic carbon will stimulate the in situ biological reduction of Cr(VI) to trivalent Cr (Cr[III]) and subsequent precipitation and fixation of Cr within the aquifer matrix as an in situ anaerobic bioprecipitation (ISAB) approach.
- The extraction/injection dynamics will help maintain the hydraulic balance inside the sheet pile enclosure around Site 114 and may also support flushing of Cr mass toward the extraction wells to speed up the reduction of Cr concentrations in the hot spots.

This design will treat the southern portion of Site 114 using ISAB and establish conditions more conducive to rapid and successful ISAB of Cr in the northern part of Site 114, which would be envisioned for the subsequent phase of the IRM. Collectively, this establishes a phasing plan for the IRM Program that will enhance the technical success of the multiple phases to achieve the most progress in the shortest timeframe and allow continuous optimization of the treatment process.

## 1.1 IRM Objectives

Active treatment performed during the phased IRM Program is envisioned to be completed over an aggressive 3-year timeframe that includes approximately 1 year of active treatment per phase. Each active treatment phase would then be followed by approximately 2 years of post-treatment monitoring. The objectives of the Phase I program are to achieve the following:

- Meaningful reductions of total Cr concentrations in groundwater:
  - In the northern portion of Site 114, reduction of Cr(VI) and total Cr from levels currently above 1,000 milligrams per liter (mg/L) via groundwater recovery to make the area more suitable for ISAB in a future IRM phase.
  - In the southern portion of Site 114, creation of an anaerobic reactive zone to support ISAB reduction of both Cr(VI) and total Cr.
  - Achieve the same within a localized area of shallow groundwater in the northern portion of Site 114.
- Document post-treatment trends showing continuing attenuation/reduction of total Cr toward the Groundwater Quality Standards (GWQS).
- Capture site-specific information on the system operation to support subsequent IRM phases.

## 1.2 Regulatory and Permitting Considerations

Because it involves injections, Phase I of the IRM will require the preparation of a New Jersey Pollutant Discharge Elimination System (NJPDES) Discharge to Groundwater (DGW) PBR Authorization Request. Pursuant to the NJPDES rules (N.J.A.C. 7:14A-7.5 and 8.5) and Technical Requirements for Site Remediation (N.J.A.C. 7:26E-5.6), this PBR Authorization Request Form is provided along with this Design document, and the detailed design describing the DGW activities are provided in this Design document.

In addition, because the DGW PBR involves operation beyond 180 days, a 45-day public notice is also required prior to the start of the groundwater discharge in accordance with 7:26E-5.6 (c)1-4. A draft notice is provided as **Appendix A**. Proof of publication will be provided to the NJDEP within 15 days after the notice is published.

Because the design also involves the withdrawal/removal of groundwater, either a Water Use Registration (WUR) or Water Allocation Permit (WAP) are required by the NJDEP Division of Water Supply (DWS). PPG currently maintains a WUR for the site (WUR100001) associated with the ongoing excavation dewatering efforts. The current WUR covers PPG Site 114 with an upper limit of total water from all diversion sources of 3.1 million gallons per month. The design for Phase I of the IRM relies on balancing the IRM-related groundwater extraction with the excavation dewatering extraction needs, such that the total dewatering will stay within the approved volumes of the current permit. The existing WUR (WUR100001) permit will be updated with the additional wells proposed for extraction purposes during the IRM, consistent with previous modifications during excavation dewatering activities.

The balance of this document provides the relevant technical background followed by the detailed design (and basis), operation, and monitoring plan for Phase I of the IRM.

# 2 TECHNICAL BACKGROUND

This section provides a brief summary of pertinent site background information, remediation history, site geology and hydrogeology, fate and transport of Cr in groundwater, and discussion of Cr treatment technologies that have been evaluated for the site. This represents the baseline information used in the IRM design.

## 2.1 Site Use, Remediation History, and Future Site Redevelopment Plans

In 1954, PPG acquired the 16.6-acre property from Natural Products Refining Company and processed chromite ore until 1963. In 1964, the plant was sold, and by 1976, chromite ore processing at the site had ceased. During the chromite ore processing operation, chromate chemical production waste (CCPW) was generated as a by-product from the production of sodium bichromate, including Chromite Ore Processing Residue (COPR), green-gray mud, and fill mixed with COPR or green-gray mud. Some of it was used as fill around the site. These materials served as an existing source of Cr impacts observed in soil and groundwater at the site.

In 1990, PPG and the NJDEP entered into an Administrative Consent Order (ACO) to investigate and remediate locations where CCPW or CCPW-impacted materials related to former PPG operations may be present. On June 26, 2009, NJDEP, PPG, and the City of Jersey City entered into a Partial Consent Judgment Concerning the PPG Sites, also referred to as the Judicial Consent Order (JCO), with the purpose of assessing the groundwater and sources of contamination at these sites as expeditiously as possible. The goal of the JCO was to complete the investigation and soil remediation activities at the PPG sites within 5 years. The selected approach for Cr-impacted soil is excavation and off-site disposal. Soil remediation at Site 114 was completed between July 2010 and January 2015. The final groundwater remedy is currently being evaluated, but this IRM is intended to advance groundwater treatment throughout all of Site 114 prior to final remedy selection.

The site is enclosed in steel sheet piling with internal shoring that bisects the site into east and west portions (**Figure 2**). The sheet pile is installed to variable depths along its length based on the site geology, with the majority of sheet pile section separating the western and eastern areas of Site 114 installed to approximately 55 feet below ground surface (bgs). Currently, the site is completely enclosed by a security fence with a main entrance gate at the intersection of Carteret Avenue and Halladay Street. A New Jersey Transit Rail Line bounds the site to the north, and a residential neighborhood is located to the west across Garfield Avenue. The southern and eastern boundary of the site is surrounded by light industrial and commercial areas near the New Jersey Turnpike Extension (Interstate 78). The eastern side of the site is the location of a former manufactured gas plant (MGP). Remediation of the MGP-impacted soils has been completed. The primary approach for soils impacted with MGP is excavation and off-site disposal.

The site is currently vacant, and remediation activities, including excavation of source mass, have been conducted at the site. The site and a few surrounding sites have been planned to be redeveloped into a multi-block retail and residential complex by the City of Jersey City and the Jersey City Redevelopment

Agency. The redevelopment will be implemented as a phased approach while the groundwater remediation is being conducted at the site.

## 2.2 Chromium Treatment Pilot Testing

In situ treatment of Cr(VI) is a well-developed technology (United States Environmental Protection Agency [USEPA] 2000), which may be implemented via biologically mediated precipitation and chemical reduction processes. Although biological and chemical treatment mechanisms differ, both treatment processes are designed to reductively precipitate and permanently fix/immobilize the Cr in the aquifer, reduce Cr concentrations in groundwater to achieve treatment goals, and support long-term treatment permanence.

Pilot scale testing was completed to evaluate the feasibility of both ISAB and in situ chemical reduction (ISCR) technologies for treatment of Cr-impacted groundwater and saturated soil at the site per the *Technical Execution Plan: Pilot Study for In Situ Treatment of Chromium Impacted Groundwater Using Reduced Iron/Free Sulfide Injections and Bioprecipitation* (AECOM 2013). These tests provided information relative to the anticipated Cr treatment performance, reagent longevity and utilization, and yielded information pertaining to fluid injection and transport within shallow and intermediate water-bearing zone geologies. The implementation and findings from these tests were used for developing the IRM remedial program and are summarized in the following sections.

### 2.2.1 In Situ Anaerobic Bioprecipitation Pilot Testing

ISAB is an established remedial technology for the treatment of groundwater. This technology employs periodic delivery of degradable organic carbon substrates, such as molasses, into the contaminated groundwater system to stimulate the native microorganisms and promote the development of an in situ reaction zone (IRZ). Within the IRZ, fermentation of the organic carbon substrate promotes development of iron- and sulfate-reducing groundwater conditions that are favorable for the reduction of Cr(VI). Under these conditions, Cr(VI) will be reduced to Cr[III] through reactions with multiple biologically-generated reductants or via direct anaerobic respiration with Cr(VI) serving as the terminal electron acceptor. Specifically, Cr(VI) will be reduced to form less soluble Cr(III)-hydroxide via the following three major reduction mechanisms:

- Direct anaerobic respiration with Cr(VI) serving as the terminal electron acceptor (e.g., enzymatic extracellular reduction and intracellular reduction [Zhu et al. 2008]).
- Reduction by sulfide (hydrogen sulfide [$H_2S$], hydrosulfide [$HS^-$]) and ferrous iron (Fe[II]). Under reducing conditions, sulfide and ferrous iron (Fe[ll]) will be produced from reduction of naturally occurring sulfate and iron.
- Formation of an iron-Cr hydroxide complex that is less soluble and more stable than pure chromium hydroxide (Cr[OH]3) (Sass and Rai 1987; Eary and Rai 1988).

The reduction of Cr(VI) to Cr(III) provides three clear benefits from a treatment perspective. First, Cr(III) is less toxic and, therefore, has higher permissible environmental concentrations. Second, Cr(III) is less soluble under site groundwater conditions and may be immobilized in the form of a hydroxide mineral that can be incorporated in a matrix of carbonate, sulfide, and other precipitates generated during the

treatment process. Finally, insoluble Cr(III) phases are resistant to re-oxidation to Cr(VI) phases under soil and groundwater conditions of the site. These factors combine to make Cr(VI) treatment via in situ anaerobic bioprecipitation an attractive remedial technology at the site.

A pilot test was completed by injection of dilute molasses solution, as an organic carbon source, into the shallow and intermediate water-bearing zone to evaluate ISAB as a technology to treat Cr(VI) in groundwater and saturated soil in an area at the northwestern part of Site 114 (**Figure 2**). This ISAB pilot test was completed per a PBR authorization and a modified PBR approved by the NJDEP on January 28 and August 12, 2014, respectively.

The results of the ISAB pilot test demonstrate that complete treatment of Cr(VI) impacts was achieved in soil and groundwater at the site using this technology. Cr(VI) concentrations were reduced below the detection limit at multiple monitoring locations through the end of the 12-month monitoring period, demonstrating the stability of the treatment.

ISAB injections were successful in stimulating the development of highly-reducing groundwater conditions. The treatment exceeded the goals of 90% reduction in Cr(VI) in groundwater and the NJDEP Non-Residential Direct Contact Soil Cleanup Criteria (NRDCSCC) of 20 milligrams per kilogram (mg/kg) in soils where organic carbon distribution was achieved. When compared to the baseline levels, rapid reduction of Cr(VI) concentrations up to 5 orders of magnitude in groundwater and 3-to-4 orders of magnitude in soil were observed in the reactive zone where organic carbon was effectively delivered. Elevated organic carbon concentrations and the established reducing conditions persisted through the end of the performance monitoring period. In addition, successful treatment in groundwater was also achieved in the anoxic fringe, where the reducing environment favorable for Cr(VI) reduction was established and in the absence of clear evidence of organic carbon delivery.

Details of the implementation and results of the ISAB pilot test are included in *The Groundwater Bioprecipitation Pilot Test Completion Report* (Arcadis 2017).

### 2.2.2 In Situ Chemical Reduction Pilot Testing

In addition to testing the biological treatment option, an ISCR pilot test was conducted to evaluate the applicability of abiotic treatment for Cr(VI) in groundwater and saturated soil at the site. This ISCR pilot test was completed per a PBR authorization approved by the NJDEP on June 2, 2015.

When compared to biological treatment, the abiotic process (chemical reduction) is implemented by introducing a reductant to chemically reduce Cr(VI) to less soluble Cr(III), which will geochemically bind onto soil surfaces in the target groundwater treatment zone (USEPA 2000). This is achieved by the delivery of the chemical reductant into the subsurface, which facilitates abiotic Cr removal similar to those described in Section 2.2.1 via conversion of Cr(VI) to Cr(III) and subsequent precipitation as either $Cr(OH)_3$ or as iron-Cr hydroxide complexes.

During the ISCR pilot test, two chemical reductants, FerroBlack®-H and calcium polysulfide (CaSx), were tested to assess the viability of ISCR at the site. Specifically,

- FerroBlack®-H was delivered into the shallow water-bearing zone of the IRM #1 area via multiple Geoprobe® direct push points and temporary wells and into the intermediate water-bearing zone of the Phase 1C area via one existing well.

- CaSx (along with sodium bicarbonate) was delivered into the intermediate water-bearing zone of the IRM #1 area via multiple injection wells.

The pilot test performance monitoring data suggested that Cr(VI) and total Cr concentrations were reduced by greater than 90% and 75%, respectively, when compared to the baseline levels. In addition, an approximately 50% reduction of Cr(VI) and total Cr concentrations in groundwater were achieved in an area where the injection of the reagent was not fully completed, when compared to the baseline levels. Cr(VI) concentrations in saturated soil were also reduced by greater than 50% of the baseline levels or remained below the NJDEP NRDCSCC of 20 mg/kg.

Overall, based on the results of this pilot test, the ISCR approach was effective and remains a viable option for Cr(VI) treatment, in addition to ISAB technology for the site. Details of the implementation and results of the pilot test are included in *The Groundwater Chemical Reduction Pilot Study Completion Report* (AECOM 2017).

### 2.2.3 Implication for IRM Design

The pilot tests were completed to evaluate the use of the ISAB and ISCR as options to address elevated Cr(VI) concentrations present in the site's groundwater. The field-scale organic carbon substrate and chemical reductant injection and performance monitoring were conducted to demonstrate the effectiveness of the techniques. The data collected during these tests have been used to support the design of Phase I of the IRM data.

The results of performance monitoring of the ISAB and ISCR pilot tests suggest that complete treatment of Cr(VI) impacts were achieved in soil and groundwater at the site using both technologies. Specifically, the test results demonstrated the following:

- Both ISAB and ISCR technologies demonstrated the capability for rapid, effective, and permanent (at least 1-year post reagent injection) Cr treatment.
- Elevated organic carbon concentrations or chemical reductant and the established reducing conditions persisted through the end of the performance monitoring period (12 months), which suggests treatment effectiveness may last for an extended period without additional reagent amendment.
- Injections were able to achieve distribution of reagent within the target footprint within the testing period. Where ISAB injection wells were used, average injection rates ranged between 0.5 and 1 gallon per minute (gpm). The flow rate observed in the intermediate water-bearing zone was lower than that observed in the shallow zone, which was attributed to the presence of finer-grained soils in the upper intermediate zone and the 10-foot injection well screens employed. To improve injectability during Phase I, increased screen lengths have been considered (20 – 40 feet) to allow broader access to intervals containing Cr and sufficient permeability to achieve distribution. Further, increased flow rates are also assumed due to the increased permeability of intermediate zone soils in the southern area of Site 114. It has been assumed that injection flow rates during Phase I will be 1 gpm based on these additional considerations and due to the hydraulic benefits provided by groundwater recirculation.

- Injection limitations during the ISAB pilot test were observed related to the fermentation of organic carbon and generation of gases within the subsurface, following sustained delivery of carbon substrate over extended timeframes. During the ISCR testing, the solid clogging of screens and surfacing under pressurized injection were observed related to the viscous nature of the blended FerroBlack©-H particulate and water mixture. These observations have been considered in development of the adaptive Phase I operational program, with adjustment of operating well locations, injection/extraction flow rates, substrate dosing, periodic well redevelopment, and supplemental fouling mitigation techniques incorporated into the existing treatment system.
- Where groundwater pH was high, the ISAB pilot test was successful in moderating pH to a circumneutral range (approximately pH 7 S.U.) which is advantageous for enhancing the long-term stability of precipitated Cr(III).

The evaluation of pilot test results (e.g., mobile porosities, injection flow rates and pressures, and reagent loading) provided design parameters for Phase I of the IRM. These design parameters provide a starting point for the well-based injection and extraction designs discussed in Sections 3 and 5 of this document.

## 2.3 Site Geology and Hydrology

The site is located on the Jersey City peninsula approximately midway between the Passaic River and the Hackensack River junction to the west (approximately 1.8 miles) and the upper bay/mouth of the Hudson River to the east (approximately 1.6 miles). Site observations from soil logs are consistent with the regional geologic mapping and include approximately 16 feet of poorly sorted fill materials over organic rich meadow mat. The meadow mat occurs throughout the majority of the site and marks the transition from the shallow fill aquifer to underlying intermediate and deep water-bearing zones.

The hydrogeologic units present at the site have been historically classified as the shallow water-bearing zone (soils and groundwater above the meadow mat), the intermediate water-bearing zone (soils and groundwater below the meadow mat to approximate depths of 37 feet bgs), and the deep water-bearing zone (soil and groundwater between 37 to 65 feet bgs). The presence and thickness of these units varies based on the relative depth to bedrock, which varies across Site 114. While not viewed as a separate hydrogeologic unit, the meadow mat that separates the shallow and intermediate water-bearing zones represents a semi-confining layer for the intermediate water-bearing zone (where present).

### 2.3.1 Shallow Water-Bearing Zone

The shallow water-bearing zone is classified as soils and groundwater above the meadow mat and is present to approximately 15 feet bgs. The meadow mat is encountered at Site 114 at elevations of 0 to -5 feet (North American Vertical Datum of 1988). The shallow fill has been excavated to a large extent as part of the soil and groundwater remediation in the shallow water-bearing zone (completed at Site 114). A clean, uniform dense-graded aggregate (DGA) was backfilled to grade and was, in some areas, complemented by a capillary cap to limit recharge and flooding. In many areas of Site 114, the backfill was amended with FerroBlack®-H to prevent the clean fill from being re-contaminated with Cr-containing groundwater from areas in which Cr remains elevated. The shallow aquifer depth to groundwater ranges from approximately 1 to 8.6 feet bgs. Current and future horizontal shallow groundwater flow is limited by the sheet pile walls, and vertical flow is limited by the meadow mat.

The meadow mat consists of silt and clay with varying amounts of organic materials; however, in some places, the organic content is low or absent. The thickness of the meadow mat varies from less than 1 foot to approximately 6 feet and exhibits reduced hydraulic conductivity compared to the shallow fill and underlying intermediate aquifer.

Shallow aquifer groundwater elevations were depressed during excavation activities and currently are being recharged by precipitation. There is negligible groundwater flow due to sheet pile controls. Shallow groundwater within the sheet pile walls can only escape through sheet pile leakage and downward vertical transport through the meadow mat or in areas where the meadow mat is absent.

### 2.3.2 Intermediate Water-Bearing Zone

The intermediate water-bearing zone at Site 114 is classified as soils and groundwater below the meadow mat and across the GAG sites is encountered to terminal depth elevation of approximately -50 feet. Within Site 114, intermediate soils are encountered at depth elevations between -20 and -30 feet. The intermediate aquifer consists of silty sand or fine-to-coarse sands with varying amounts of silt and gravel. The top of the granular soils is encountered below the meadow mat, with an observed vertical thickness of 5 to 20 feet.

The hydraulic gradient in the intermediate aquifer is east-southeast or southeast and ranges from 0.004 feet per foot (ft/ft) to 0.002 ft/ft (March 2017 data). The estimated hydraulic conductivity in the intermediate water-bearing zone is up to approximately 5 feet per day (ft/day), and estimated seepage velocity is approximately 0.02 to 0.04 ft/day. The flow is likely to be affected by leaking sheet pile and recharge associated with the nearby diabase contact parallel to Garfield Avenue. There is an observed upward hydraulic gradient from the lower permeable, deeper aquifer to the intermediate aquifer, further supporting the potential for higher degrees of volumetric flux in the intermediate aquifer.

### 2.3.3 Deep Water-Bearing Zone

The deep water-bearing zone is classified as soils and groundwater below the intermediate zone and to the top of either regional till or bedrock. The deep water-bearing zone is encountered at the GAG sites to a terminal depth elevation of approximately -65 feet, and within Site 114 to a terminal depth elevation of approximately -50 feet. The deep aquifer consists of varying mixes of sand, silt, and clay. The deep aquifer has been characterized in vertical aquifer profiling (VAP) logs and soil borings as containing variable relative hydraulic conductivities that reflect changes in granular and fine-grained sediments. The deep aquifer exhibits relative hydraulic conductivities of up to approximately 5 ft/day.

Depending on location, the deep aquifer hydraulic gradient is east, east-southeast, and southeasterly and is about 0.005 ft/ft. The VAP logs indicate that the hydraulic conductivity of the deeper aquifer is variable and reflects the variable proportions of fine soil materials. Therefore, the seepage velocities in the deep aquifer may range about an order of magnitude from 0.004 to 0.04 ft/day.

Groundwater elevation data collected from shallow, intermediate, and deep water-bearing zones in December 2016 and the iso-potentiometric contour maps developed with these data are shown on **Figure 3.**

### 2.3.4 Aquifer Testing Results

To evaluate achievable groundwater extraction rates and water table drawdown within the vicinity of a pumping well, a pump test was completed by AECOM in the northern area of Site 114, east of the pilot test area (AECOM 2015).

A step drawdown pump test, a 3-day constant rate pump test, and a recovery test (to monitor the time taken for water levels to resume to original conditions observed prior to pumping) were completed between November 4 and November 17, 2014. These tests were conducted by extracting groundwater from the intermediate water-bearing zone well 114-MC-EW-103 (**Figure 2**). During the pumping test, a sustained groundwater pumping rate of approximately 3 gpm was achieved in 114-MC-EW103 over a period of 72 hours. Drawdowns at the monitoring wells were found to range between 25 feet (at the pumping well) to 4 feet (at an intermediate well located 27 feet away). No measurable water level drawdowns were observed at monitoring wells located more than 27 feet from the extraction well.

Hydraulic conductivity estimates from both the pumping and recovery tests were found to range from 1 to 5 ft/day for the intermediate water-bearing zone. These estimates are consistent with representative values for silt and loess sediments, which were the main soil types observed across the well screens.

The observed sustainable pumping rate of approximately 3 gpm has been used for the groundwater extraction rate design and as the basis for the groundwater model development for Phase I of the IRM, as discussed in Section 3.1.1. These data will be further verified and refined during the extraction and injection testing as the part of the confirmatory data collection effort, as discussed in Section 2.5.2.

## 2.4 Nature and Extent of Chromium Impacts

### 2.4.1 Chromium in Groundwater

The primary site contaminant of concern (COC) in groundwater is Cr. Total Cr and Cr(VI) have been detected in shallow, intermediate, and deep groundwater water-bearing zones at the site at concentrations exceeding the GWQS of 70 micrograms per liter (µg/L). Recent total Cr and Cr(VI) concentrations and iso-concentration contour maps for the shallow, intermediate, and deep water-bearing zones are presented on **Figures 4** through **9**, respectively. As shown on **Figures 4** through **9**, both total Cr and Cr(VI) are primarily present in the intermediate water-bearing zone with a reduced footprint and magnitude observed in the deep water-bearing zone at Site 114. As Cr within the shallow water-bearing zone has been excavated, concentrations above the GWQS were only observed at a few localized areas at the site. Groundwater within the intermediate and deep water-bearing zones at Site 114 is confined by the existing sheet pile enclosures that reduce the likelihood of Cr transport in groundwater. The historical total Cr and Cr(VI) data in groundwater are provided in **Appendix B**.

*Shallow Water-Bearing Zone*

The concentrations of Cr in the shallow water-bearing zone prior to the excavation work ranged from less than 1,000 micrograms per liter (µg/L) to 16,000,000 µg/L. The concentrations of both total Cr and Cr(VI) and the areas with concentrations exceeding the GWQS of 70 µg/L for total Cr have been reduced as a result of shallow water-bearing zone soil excavation and treatment of backfilled FerroBlack®-H material. The current distribution and concentrations of total Cr and Cr(VI) in the shallow water-bearing zone are

shown on **Figures 4** and **5**, respectively. As shown on **Figures 4** and **5**, total Cr and Cr(VI) concentrations have been reduced below the 70 µg/L in most areas at Site 114, except for the pilot test area located in the northwestern portion of Site 114 and in localized areas surrounding monitoring wells 114-P2B1-MW102S, 114-P1B-MW102S, 114-P2A-MW104S, and 114-MW25A. In addition, total Cr and Cr(VI) concentrations remain elevated along the light rail line, beneath the Carteret Avenue, and at a few localized areas outside of Site 114. Except for the pilot test area, areas within Site 114 that contain total Cr and Cr(VI) above the GWQS are in areas backfilled with FerroBlack®-H material. Continued Cr treatment in the presence of FerroBlack®-H material in these areas is expected to continue over time. Residual Cr impacts in the pilot test area, where no FerroBlack®-H is present, will be treated with supplemental IRM polishing treatment as discussed in Section 4.

*Intermediate Water-Bearing Zone*

Cr concentrations at intermediate water-bearing zone monitoring wells, between 2015 and 2016, ranged from less than 1,000 µg/L to 1,000,000 µg/L, except for a total Cr concentration of 1,320,000 µg/L detected at 114-P2B1-MW101I in June 2016. VAP sampling activities completed in May and June 2015 indicate that total Cr and Cr(VI) concentrations above 1,000,000 µg/L were present in the same area (northeastern portion of Site 114). Total Cr and Cr(VI) concentrations were detected as high as 5,720,000 µg/L and 5,370,000 µg/L, respectively, at VAP location 114-VAP-6. It is anticipated that these concentrations represent the baseline for IRM Design.

The current distribution and concentrations of total Cr and Cr(VI) in the intermediate water-bearing zone are shown on **Figures 6** and **7**, respectively. As shown on **Figures 6** and **7**, the Cr concentrations and the footprint of the Cr-impacted area are stable and well-aligned with the sheet pile enclosures installed around the site boundaries. These observations suggest that the sheet pile enclosures effectively limit the migration of Cr off site.

In the northwestern portion of the site, where the ISAB and ISCR pilot tests were completed, total Cr and Cr(VI) concentrations have been reduced below the 70 µg/L GWQS for total Cr (**Figures 6** and **7**), where reagent distribution and/or geochemical reducing conditions were achieved.

*Deep Water-Bearing Zone*

The distribution of total Cr and Cr (VI) in the deep water-bearing zone are observed across a smaller spatial footprint and are lower in concentration when compared to the extent of Cr in the intermediate water-bearing zone. Cr concentrations exceeding the 70 µg/L GWQS for total Cr were detected along the center of Site 114 at MW6C in March 2016, with the highest concentrations of total Cr and Cr(VI) detected at 9,890 µg/L and 10,400 µg/L, respectively. The current distribution and concentrations of total Cr and Cr(VI) in the deep water-bearing zone are shown on **Figures 8** and **9**, respectively.

### 2.4.2 Chromium in the Soil

Cr impacts in shallow water-bearing zone soils have been removed via excavation, and soil concentrations in exceedance of the NRDCSCC have been identified within the intermediate and deep water-bearing zones. These exceedances are attributed to the high dissolved-phase concentrations that result in an elevated saturated soil sample response. As soil Cr impacts in the intermediate and deep water-bearing zones become in equilibrium with groundwater, soil impacts are expected to be treated via the groundwater IRM Program. The historical total Cr and Cr(VI) data in soil are provided in **Appendix B**.

### 2.4.3 Other Contaminants

Additional contaminants historically detected above the applicable GWQS values at Site 114 include Target Analyte List (TAL) metals, cyanide, petroleum hydrocarbon compounds, volatile organic compounds (VOCs), and semi-volatile organic compounds (SVOCs) associated with former MGP operations. While metals have been detected across Site 114, VOCs and SVOCs were primarily observed at localized areas in the eastern portion of the site (e.g., 114-MW20B). Based on the most recent sampling events (2015 or 2016), the following COCs were detected above the GWQS values:

- Metals – aluminum, antimony, arsenic, beryllium, cadmium, copper, iron, lead, manganese, nickel, selenium, silver, sodium, thallium, and vanadium
- VOCs – benzene, ethylbenzene, and trichloroethene
- SVOCs – bis(2-ethylhexyl)phthalate, benzo(b)fluoranthene, benzo(a)anthracene, and benzo(a)pyrene

While the concentrations of these COCs were lower compared to Cr and are not the primary targets of the IRM Program, these additional COCs have been considered as part of the IRM Program development and will be addressed via IRM treatment operations. These contaminants are expected to be treated with the existing treatment plant (e.g., via metal precipitation, granular activated carbon [GAC] adsorption, and filtration) or may be otherwise utilized as supplemental organic carbon substrates for ISAB or via natural biological degradation (e.g., VOCs and SVOCs). The historical data for these additional contaminants are provided in **Appendix B**, with a general summary of the most notable COCs observed in the intermediate and deep water-bearing zones included below.

- The average concentration of arsenic was 112.7 µg/L among the detected concentrations in the intermediate and deep water-bearing zone monitoring wells in 2016; while the maximum detection was 484 µg/L in GPS-IW4I in April 2016, most detections were below 300 µg/L in 2016.
- The average concentration of lead was 16.1 µg/L among the detected concentrations in the intermediate and deep water-bearing zone monitoring wells in 2016; while the maximum detection was 156 µg/L in 114-P2B4-MW101I in March 2016, most detections were below 30 µg/L in 2016.
- The average concentration of copper was 121.4 µg/L among the detected concentrations in the intermediate and deep water-bearing zone monitoring wells in 2016; while the maximum detection was 2,290 µg/L in 114-P2B1-MW101I in March 2016, most detections were below 500 µg/L in 2016.
- The average concentration of manganese was 1,793 µg/L among the detected concentrations in the intermediate and deep water-bearing zone monitoring wells in 2016; while the maximum detection was 34,000 µg/L in 114-P2A-MW102I in December 2016, most detections were below 6,000 µg/L in 2016.
- The average concentration of nickel was 62.9 µg/L among the detected concentrations in the intermediate and deep water-bearing zone monitoring wells in 2016; while the maximum detection was 945 µg/L in 114-P2B1-MW101I in June 2016, most detections were below 300 µg/L in 2016.
- The average concentration of benzene was 318.5 µg/L among the detected concentrations in the intermediate and deep water-bearing zone monitoring wells in 2015; while the maximum detection was 1,170 µg/L in 114-MW20B in October 2015, most detections were below 70 µg/L in 2015.

- The average concentration of naphthalene was 459.9 µg/L among the detected concentrations in the intermediate and deep water-bearing zone monitoring wells in 2015. While the maximum detection was 1,070 µg/L in 114-MW20B in October 2015, most detections were below 12 µg/L in 2015.

Except for manganese, the maximum concentrations of all above COCs are below the permitted effluent limitations for the water treatment system. As detailed in Section 3.1.3, operation of the water treatment system has been effective in reducing these concentrations prior to historical discharge, and ongoing monitoring of these COCs to demonstrate that sufficient treatment is achieved for reinjection use will be conducted over the course of the IRM.

## 2.5 Confirmatory Data Collection

Pilot test results and historical site data have provided information to support development of the Phase I IRM Program. To further refine the approach and ensure its overall success, the collection of additional soil and hydrogeologic data are planned as part of IRM implementation to confirm remedial well design specifications and to improve the understanding of heterogeneity of geological formation and variation of hydrogeological behavior across the IRM Phase I area. As discussed in Sections 2.2 and 2.3, previously completed pumping test and injection pilot tests performed within the northwestern portion of Site 114 demonstrated that sustainable extraction rates of approximately 3 gpm (Section 2.3.4) and injection rates of up to approximately 1 gpm (Section 2.2.3) could be achieved.

VAP data collected during 2015 demonstrate that the relative permeability of soil materials present within the intermediate and deep water-bearing zones are variable across the site and suggest that variability in achievable injection and extraction flow rates are anticipated as part of IRM implementation. From a design standpoint, confirming the achievable flow rates for each of the areas targeted during IRM Phase I operation is considered a critical step to optimize the remedial well network and overall IRM performance. As treatment performance and IRM Phase I operational timeframe requires introduction of sufficient volumes of organic carbon and treated groundwater into the subsurface, verifying the existing understanding of the hydrogeological information is critical to refine the design and to ensure overall IRM Phase I success.

While it is critical to design refinement and eventual IRM Phase I remedial outcomes, collection of this hydraulic information is not required for PBR and IRM Phase I Work Plan approval. Therefore, Arcadis recommends performing the confirmatory data collection activities following the submittal of the PBR Authorization request to expedite IRM Phase I implementation. Developed to enable adaptive modification or alteration over the course of the Phase I program, this IRM design document acknowledges the collection of supplemental information during procurement and implementation phases for updating the dynamic recirculation simulations and to adjust the well network, as necessary.

Arcadis' proposed confirmatory data collection activities include the following primary elements:

- Installation of four multi-purpose (injection and extraction) Phase I remediation wells for groundwater extraction and clean water injection tests to verify geological and contaminant distribution.
- Completion of groundwater extraction and clean water injection tests to verify sustainable extraction and injection rates at each of the four well locations to refine Phase I well design.

The updated hydraulic information collected via the above tests will be integrated into the dynamic groundwater recirculation flow and solute transport model to provide final specifications for the Phase I well network. As applicable, the total number of injection and extraction wells may be increased or decreased and well locations may be modified to account for observed flow rates.

The following summarizes the proposed Arcadis activities performed as part of this supplemental testing.

### 2.5.1 Well Installation and Construction Parameter Sampling

Four locations are proposed for test well installation and pre-design testing. Each of these locations are intended to be included as part of the IRM Phase I well network and will be designed to accommodate either injection or extraction functions. Two of these locations are proposed in the northeast portion of Site 114 (initially targeted for extraction during Phase I), and two will be positioned within the southwest and southeast, as shown on **Figure 10**. Two of the four new wells will be located in areas where existing monitoring wells are present and available for use in assessing extraction drawdown and injection hydraulics. Wells will be installed with well screen placement determined from historical information and drilling observations, with at least one of the two wells in each area encompassing the intermediate and deep water-bearing zones (or both, if applicable). The construction details of the proposed pre-design testing wells are included in **Table 1**.

Specifically, wells will be constructed as follows:

- Borings will be advanced using the hollow stem auger (HSA) drilling techniques or similar drilling technologies. During drilling, soil samples will be collected via split spoon sampling both from depth intervals to confirm the bottom of the meadow mat and from depth intervals targeted for well screen placement. Up to five split spoon samples will be collected from each drilling location.
- To support IRM Phase I well construction specifications, two soil samples will be collected from intervals within the screened interval at each new well for analysis of soil gradation (sieve and hydrometer analysis). Sample intervals will be selected to represent the fine and coarse portions of the intermediate and deeper aquifers. Field observations of soil properties will be used as a design basis for the test injection/extraction well screen and filter pack placement. Soil samples selected for laboratory physical properties testing, especially information related to the finer grained fraction, will be used as a conservative design basis for the Phase I injection and extraction wells.
- While detailed lithologic logging during drilling will be used to finalize the exact intervals for test well screen installation, it is assumed that intermediate water-bearing zone pre-design wells will be constructed with 4-inch stainless steel, 10-slot, 20-foot screens at approximate depths between 20 to 40 feet bgs.
- For pre-design purposes, it is assumed that two deep water-bearing zone wells will be constructed with 4-inch stainless steel, 10-slot, 20-foot screens between 45 to 65 feet bgs.
- Wells will be completed with schedule 40 polyvinyl chloride (PVC) risers and stickups approximately 2 to 3 feet above ground surface.
- The well construction design is based on the current understanding of contaminant distribution and hydrogeological characteristics in the intermediate and deep water-bearing zones and may be adjusted based on field observations. The annular space will be filled as follows:

- #0 filter sand extending from the bottom of the boring to 1 or 2 feet above the screen.
- Hydrated bentonite (1 foot).
- Neat Portland cement grout extending to 3 feet bgs.

For the intermediate depth test wells, the hydrated bentonite and neat Portland cement grout placement will be designed to limit pumping and injection-related hydraulic short circuiting between the shallow- and intermediate-depth aquifers. The well seal will be constructed at or below the bottom of the meadow mat or, in the absence of the meadow mat, below the fine-grained soils, if present. Other modifications may be made to the well construction specifications detailed above (e.g., filter pack selection, completion elevation) based on soil cutting and drilling observations.

Following installation and annulus curing, the wells will be developed using surge and pump techniques, including a double 4-inch surge block and a submersible pump capable of variable pumping rates from 0.5 to 5 gpm. The well development will include removing a minimum of three well volumes while observing field parameters, including temperature, specific conductance, pH, and turbidity. Initial groundwater drawdown and sustainable pumping rate information will be assessed during well development at variable flow rates of 33%, 67% and 100% of the max expected sustainable extraction rates (1 gpm, 2 gpm, and 3 gpm) to inform the pump rates associated with the pre-design step tests and long-term, sustained-rate pump tests.

### 2.5.2 Extraction and Injection Testing

Two of the four test well locations will be positioned with nearby monitoring wells to evaluate draw down. The existing monitoring wells are located at distances between approximately 20 to 80 feet away from the planned test wells. They correspond to one to two times the estimated saturated thickness of the intermediate or deep aquifers and are consistent with observed radius of influence drawdowns during the 2015 pump test (AECOM 2015).

The extraction and injection testing is intended to provide hydraulic data to support the final injection and extraction well network design, including the following:

- Hydraulic conductivity ranges and ability to extract and inject water to refine the number of wells required to successfully distribute carbon amendment within the desired timeframe.
- Ratio of extraction-to-injection flow rates and well numbers, expected to range from 1:1 to 1:3.
- Ability to limit hydraulic communication with the shallow aquifer.
- Presence of significant hydraulic conductivity gradient between the intermediate and deep aquifers that will inform design of injection/extraction well screen lengths;
- Water quality during extraction and volume of water to be handled by the treatment system.
- Representative geochemical parameters (e.g., dissolved iron and manganese) concentrations to assess potential fouling concerns during Phase I.

### 2.5.2.1 Step Pumping Test

Based on the known hydraulic conductivity ranging from 1 to 5 ft/day and the AECOM pump test (AECOM 2015), the maximum pumping rate at each well is expected to be approximately 3 gpm. The maximum pump rate will be further evaluated during the well development, as discussed in Section 2.5.1. Step pumping tests are most commonly run with three steps at 33%, 67%, and 100% of the anticipated maximum pumping rate of the well.

The procedure outlined below is in accordance with the requirements of the Arcadis Pumping Test Standard Operating Procedures included as (**Appendix C**). The first step is to operate the pump at a rate of approximately 1 gpm. Additional steps will be evaluated based on the response observed during the first step. Each step will be allowed to run for a maximum of 2 to 3 hours for a total maximum pumping time of 9 hours. Pumping will be set and maintained at constant rates and precisely measured using a manometer. Water generated during the step tests will be transferred to the existing treatment system for treatment at the site.

Following shutdown of the pumping well, recovery of the water level will be recorded until the water level recovers to within 90% of the original static condition or for a maximum of 2 hours. Pressure transducers will be set to collect water level data at 5 second intervals throughout the duration of the step pumping test.

Manual water level readings will be collected at the test well for backup and calibration of the pressure transducer data. Manual water level readings will be recorded at the pumping well at the following intervals for each step:

| Elapsed Time (minutes) | Interval Between Manual Measurements (minutes) |
|---|---|
| **0 to 5** | 1 |
| **5 to 15** | 2 |
| **15 to 60** | 5 |
| **60 to 120** | 10 |

Manual water level readings will also be collected from the monitoring wells as frequently as practical to provide a backup to the pressure transducer data. The plotted results of a step pumping test will be used to select the discharge rate for a follow-up constant rate pumping test.

### 2.5.2.2 Constant Rate Pumping Test

After the completion of the step pumping test, a constant rate pumping test will be completed at each test well for a duration of approximately 36 to 48 hours. The flow rate for the constant rate test will be selected based on the results of the step pumping test. The exact duration of the test will be determined by evaluating the drawdown curves. The goal of the testing would be to achieve a steady state pumping

condition at the selected pumping rate for a minimum period of 12 hours and determine the maximum pumping capacity of the intermediate and deep aquifer. Pumping rates will be selected so as not to expose or dewater the pumping well screen. Pressure transducers in the test well and surrounding monitoring wells will be set to record data at 10 second intervals. Additional manual readings will be collected at the pumping well and surrounding monitoring wells at the following frequency:

| Elapsed Time (minutes) | Interval Between Manual Measurements (minutes) |
|---|---|
| **0 to 5** | 1 |
| **5 to 15** | 2 |
| **15 to 60** | 5 |
| **60 to 120** | 10 |
| **120 to 240** | 30 |
| **240** to completion | 60 |

Pumping will be set and maintained at constant rates, and measured using a manometer. Water generated during the constant rate tests will be transferred to the existing treatment system for treatment at the site.

During the constant rate extraction test, total Cr, Cr(VI), and total iron samples will be collected at the beginning of the test, near the mid-point, and at the conclusion of the test.

#### 2.5.2.3 Constant Rate Injection Test

The injection tests will be conducted at constant rates for a duration of up to approximately 36 hours in the four test wells. The exact duration of the test will be determined by evaluating the groundwater elevation within the injection test well and associated monitoring wells. The goal of the testing will be to achieve a steady-state water level at the selected injection rate for an extended period of time and to determine the overall injection capacity of the intermediate and/or deep aquifer at each location. The injection rate will be selected based on the results of the pumping test and adjusted based on observed head rise, if appropriate. Water for the tests will be obtained from the on-site public water supply and will be conveyed in temporary above-grade piping to each test well.

The pressure transducer within the test well will be set to record data at 10 second intervals during the test. The pressure transducer within the test injection well should be isolated within a 1-inch stilling well consisting of PVC pipe lowered to several feet below the initial water table. This will eliminate the noise and turbulence associated with water cascading into the well. Injection rates will be set and maintained at constant rates and measured using a manometer.

In addition to the pressure transducer data, manual water level data will be collected at the test well for backup and to calibrate the pressure transducer data. Manual water level readings will be recorded at the injection well and surrounding monitoring wells at intervals consistent with the steady-state extraction test outlined above.

#### 2.5.2.4 Geochemical Testing

Each of the four pre-design testing wells will be sampled prior to the extraction and injection tests to analyse for multiple water quality parameters that will be used to develop the final design and operation of the groundwater treatment system. Sampling will be completed prior to extraction and injection testing to represent baseline aquifer conditions. A three-volume-purge methodology will be used as it will better reflect actual system influent conditions from the pumping extraction wells than other methods.

The sampling and analytical methods will follow NJDEP standards, and standard analytical and reporting times are assumed. The groundwater samples will be analysed at a New Jersey-certified laboratory for a suite of analyses that includes relevant groundwater contaminants and groundwater quality data. The analytical suite for each of the four testing wells will include the following:

- VOCs and SVOCs
- TAL metals (total and dissolved)
- Cr(VI) (total and dissolved)
- Sulfate
- Total organic carbon (TOC)
- Field parameters (pH, conductivity, dissolved oxygen [DO], turbidity, oxidation-reduction potential [ORP], etc.)

The groundwater analytical data will be used for selecting, sizing, and optimizing the necessary treatment process steps and chemical amendments for the treatment system operation, as described in Section 3.1.3. While historical operation of the water treatment system has demonstrated significant removal efficiency for Cr, VOCs, SVOCs, and other metals in groundwater, supplemental sampling from these locations will further inform system design requirements. This groundwater data will also be used to identify system, subsurface scaling, or fouling issues for the IRM Program operation and to determine the means to mitigate those issues.

# 3 PHASE I IRM DESIGN: INTERMEDIATE AND DEEP WATER-BEARING ZONES

Activities proposed as part of the IRM Phase I and summarized in this PBR request include the following:

- Implementation of ISAB to initiate and sustain biological treatment in the southern half of Site 114 while leveraging groundwater extraction within the northern part of Site 114 to remove Cr mass.
- Extraction and reinjection activities included as part of the Phase I IRM are designed to address intermediate and deep groundwater horizons, utilizing both biological degradation and physical extraction means.
- In conjunction with these activities, supplemental injection activities are being proposed for shallow water-bearing zone treatment to promote localized treatment in an area that contains residual Cr.

Each of these PBR elements are presented in the sections below.

## 3.1 IRM Design Basis and Infrastructure

The ISAB treatment program builds on successful results achieved during pilot testing activities. The IRM Phase I program will rely on an injectable organic carbon substrate (e.g., molasses, emulsified vegetable oil [EVO]) to establish reduced geochemical conditions and to stimulate the native microbial community to support reduction of Cr(VI) to Cr(III). As detailed in Section 2.2, this process is facilitated by several primary mechanisms that foster the precipitation and fixation of Cr(III) in aquifer soils. To achieve ISAB treatment within the southern area of Site 114, the IRM Program has been developed with a well network designed to allow sustained delivery of treated groundwater that has been amended with organic carbon into the subsurface. Groundwater extraction activities concurrent with ISAB reinjection will serve the following primary objectives:

- Provide a source of water for sustained ISAB injections.
- Maintain hydraulic conditions within the Site 114 sheet pile to limit mounding during sustained injection activities.
- Support removal of Cr(VI) concentrations from the northern portion of Site 114.

As demonstrated during the pilot test, the propagation of both organic carbon and reduced groundwater chemical species (e.g., ferrous iron, sulfide) through the subsurface collectively support Cr(VI) to Cr(III) reduction and precipitation (Arcadis 2017). To accomplish this, the proposed well network will be used adaptively over the course of operation in conjunction with systematic modification of extraction and reinjection flow rates, well configuration (i.e., extraction or injection), and organic carbon dosing. The recommended well network was developed based on incorporating existing site information into a groundwater and solute transport model (Section 3.1.1). This model was used to determine specifications for well spacing, vertical installation, and operational sequencing based on previously identified hydraulic information. These hydraulic parameters will be further verified and refined during confirmatory testing activities outlined in Section 2.5.2. The following sections present the modelling and design basis and the Phase I well network, water treatment, and conveyance infrastructure specifications.

### 3.1.1 Recirculation Flow and Solute Transport Modelling

Historical geologic and hydraulic information was utilized to develop an appropriate design well network capable of establishing a complete reactive zone within targeted intermediate and deep water-bearing zones over an initial 6-month period within the Phase I IRM treatment footprint. A groundwater flow and solute transport model was constructed for Site 114 to assess the necessary spacing, orientation, and operational sequencing of the Phase I well network (**Appendix D**). The modeling approach allowed verification of the combination of extraction and injection activities at Site 114 that avoid excessive hydraulic mounding within the sheet pile walls while achieving organic carbon distribution during the Phase I operational timeframe. Finally, the model serves as a tool for future optimization of the Phase I program based on additional groundwater extraction and injection information generated over the course of operation.

As detailed in **Appendix D**, MODFLOW was selected for the construction of the numerical groundwater flow model at the site. The model extents are limited to the Site 114 boundary that follows the perimeter sheet pile walls as they effectively hydraulically control the majority of the site. The model is composed of four vertical layers that discretely represent the shallow fill, meadow mat, intermediate, and deep aquifers. The base of the model represents the contact between the bottom of the deep aquifer and the underlying till and/or bedrock. Hydraulic parameters, such as hydraulic conductivity and recharge, were assigned within ranges of observed values based on site slug tests, aquifer tests, and literature values. Iterative remedy simulations were then conducted to evaluate the temporal change in heads during remedy operations. Once the groundwater flow model was constructed, solute transport modeling was performed using Modular 3-D Transport Model (MT3D) and MT3D Multi-Species (MT3DMS). The solute transport modeling was used to represent the development of the ISAB reactive zone based on carbon substrate injection simulations during the first 6 months of Phase I operations.

The groundwater flow and solute transport model were used to identify an IRM design consisting of 35 injection well and 7 extraction well positions. The injection wells are located on the southern half of Site 114 within the Phase I area. The southern well network includes variable sequencing that utilizes wells operated for injection purposes and wells that are shifted from extraction to injection purposes to control hydraulic mounding during different steps of the Phase I program. Dedicated Phase I extraction wells are located on the northern half of Site 114 and are located in areas of highest observed Cr concentrations to maximize mass removal.

Iterations of the site-specific injection and extraction flow rates and the Phase I well network indicated that a combined total injection and extraction rate of 17 gpm can achieve organic carbon distribution within the southern area of Site 114 during the first 6-month period. While this flow rate was acceptable for modelling purposes, it is anticipated that wells will behave differently based on unique geologic heterogeneities in different areas of the site. It is also assumed that, where achievable, injection and extraction rates will be increased to maximize the total quantity of groundwater extracted and injected within system capabilities (40 gpm) and up to permit specifications. Over the first 6 months of operation, the Phase I design entails initiation of injection activities within the southern end of Site 114, followed by gradual northward shifts in operating wells during three, 8-week cycles. Following this 6-month period, additional cycles are anticipated to replenish organic carbon substrates and address residual Cr concentrations.

The model developed for Phase I operations will be leveraged to review and refine remedial operations based on additional information obtained during hydrogeologic testing, hydraulic monitoring, and water quality monitoring during confirmatory testing activities, remedial well infrastructure installation, and Phase I operation. This information will enable use of the model as a predictive tool or to evaluate remedy performance, acknowledging that monitoring information will be used to demonstrate overall treatment extent and adapt remedial operations.

### 3.1.2 Extraction and Injection Well Design

The number and location of injection and extraction wells were determined based on groundwater flow modelling, the distribution of Cr in intermediate and deep water-bearing unit groundwater, and the site-specific geology. The model indicates that a total number of 35 injection well positions and 7 groundwater extraction well positions are necessary. Each position is assumed to entail discrete screened intervals in both the intermediate and deep water-bearing units. While this results in 70 total injection wells and 14 extraction wells, confirmatory testing activities performed in advance of the full-scale well network will provide increased hydraulic data resolution in each area of the site targeted for remediation during Phase I (Section 2.5). These data will be used to refine the overall understanding of differences in injection or extraction rates based on the variable hydrogeology and will enable more specific model refinement to verify that the proposed well network is appropriate to achieve the IRM objectives. The layout and vertical interval specifications for IRM Phase I extraction and injection wells are, therefore, considered to be a conceptual representation of the final network, with further refinements made following pre-design testing and in response to drilling observations during well installation. For PBR approval purposes, it is assumed that up to 100 total injection wells and 25 total extraction wells will be installed. The proposed IRM Phase I remedial well layout is shown on **Figure 10**, and the well construction details are included in **Table 1**. The final number of injection and extraction well locations will be finalized based on the following:

- Pre-design testing (including drilling and test well installations, soil gradation and hydrometer physical properties testing, and the hydraulic testing program).
- Inferences from the conceptual site model, including the updated Enhanced Visualization System (EVS) 3-D model.
- Field observations during the drilling of each injection and extraction well.

The conceptual design of the extraction and injection well completions are summarized on **Figure 11** and include the following:

- 6.25-inch inner diameter HSA drilling or using similar drilling technologies to targeted termination depth with 2 feet split spoon at selected depth intervals to confirm geology.
- 4-inch stainless steel screen (10-slot with #0 sand pack).
- Schedule 40 PVC riser to approximately 3 feet above ground or completed with flush mount well vaults.
- The wells will be finished with stick up mounts or completed with flush mount well vaults and insulated. Locking covers will be placed over each wellhead assembly.

During well completion, hydrated bentonite and grout will be used to seal the annulus to the surface. Borings from each well will be considered to ensure a competent seal with the meadow mat to eliminate hydraulic communication between the shallow and intermediate aquifers. While stick-up well construction is currently considered a part of the design, the option of using flush mount completions will be reviewed during the final wellhead and system conveyance infrastructure design. Final well completion determination will also account for surface elevation changes during regrading activities performed during site restoration activities. As applicable, protective bollards may also be installed to prevent well damage during the IRM.

For the purposes of this PBR, individual well screen lengths are proposed to be between 20 to 40 feet in length, which will be further refined based on results from the pre-design testing program, the soil lithology observed during drilling activities, the distribution of Cr, and the updated conceptual site model (CSM). To conceptually demonstrate this, a diagram showing the orientation of IRM Phase I remediation well screens with the Site 114 geology and Cr distribution is shown on **Figure 12**. The extraction well pumps will be set at the midpoint of the screened interval, and drawdown will be adjusted and controlled by readings from a pressure transducer installed at the top of the screened interval. This is intended to limit over pumping the extraction wells, to limit exposing the screen to air (and oxygen), and to control well fouling. Based on previous hydraulic testing, it is assumed that extraction rates will operate at 3 gpm. Where feasible, extraction rates will be increased based on the specific capacity of the aquifer at a given well location.

The injection wells will be equipped with a drop tube to approximately 2 feet below the seasonal low groundwater elevation to convey the injected recirculation water and carbon amendment to the saturated interval and thereby limit aeration of the injection water and bubble entrainment within the reinjection stream. Injection by drop tube also provides greater resilience for well fouling. Each active injection well will be equipped with a pressure transducer installed at the top of the screened interval to monitor the water level at the well. Based on previous testing at the site and the common ratios of injection well capacity relative to injection wells, it is estimated that injection rates may vary between 0.5 to 3 gpm per well. Similar to extraction operations, injection wells may be operated at higher flow rates, depending on the nature of the soil formation and ability to receive fluids.

### 3.1.3 Ex Situ Groundwater Treatment

The ex situ treatment system will be used to handle extracted groundwater for treatment, carbon substrate amendment, and injection to support the IRM ISAB recirculation approach. Treatment system operation will be conducted in accordance with the existing WUR for the site (WUR100001), with the treatment train qualified to address an anticipated extraction and injection flow rate of 40 gpm. For PBR purposes, it is assumed that Phase I operations will entail 40 gpm of total system flow over 12 months of operation, resulting in a total recirculated volume of 21 million gallons. This equates to approximately 1.75 million gallons per month, which is within the WUR permit specifications and still leaves capacity for excavation dewatering needs, as necessary.

As detailed in Section 2.4.3, the primary COCs are elevated levels of Cr(VI), up to or above 1,000,000 µg/L; low levels of other metals; VOCs; and SVOCs. The current water treatment system has been used effectively to achieve removal of these target COCs and comply with permit requirements during previous excavation dewatering activities. These activities have been conducted in areas of the shallow water-

bearing zone where these other metals, VOCs and SVOCs are observed at considerably higher concentrations than those identified in the intermediate and deep water-bearing zones. As an example, the maximum influent concentration of total VOCs and SVOCs considered in the WUR permit were 18.87 mg/L and 5.88 mg/L, respectively – concentrations that are higher than the highest concentrations observed within the intermediate and deep water-bearing zones.

Over the course of operation, the water treatment system will be monitored for flow rate and treatment management. The conservative 40 gpm flow rate proposed for the IRM still accommodates sufficient system capacity within the WUR for anticipated excavation dewatering needs. There may be transient or sporadic occurrences where excavation dewatering needs to be increased to accommodate recharge from significant storm events, and total IRM flow rates during these potential durations can be temporarily reduced to remain within the WUR. Treatment system management includes ongoing review of influent and effluent COC concentrations at the water treatment plant to ensure that reinjected water meets the requirements of the PBR. The treatment of COCs in the effluent groundwater used for reinjection will be sufficient to achieve either 95% reduction of influent levels or below the applicable GWQS values, whichever is less stringent. Based on the groundwater sourced to the treatment system, a review of individual COCs will be performed to ensure that these treatment objectives are met. In the event that shallow groundwater from areas containing elevated metals, VOCs, or SVOCs is being delivered to the treatment system, supplemental polishing steps (adsorption) may be used to address these impacts or groundwater from these areas may be temporarily diverted from the IRM recirculation water sources. The water treatment train will consist of the following basic unit process elements:

- Groundwater extraction
- Chemical reduction (Cr[VI] removal)
- Aeration (metals removal)
- Chemical amendment (biological inactivation)
- Phase separation (solids removal)
- Adsorption (VOC removal and Cr[VI]/metals polishing)
- Chemical amendment (organic carbon amendment)
- Amended water injection
- Residuals management (solids thickening, dewatering, and disposal)

The treatment system will facilitate continuous operation while minimizing operator input and manual system operations to the extent practical. Similar to previous site operations, dewatered treatment residuals will be stored on site prior to off-site disposal. Many of the above components are similar to the existing water treatment system currently present on site for treatment of extracted groundwater. The additional unit process considerations include an aeration step to enhance iron removal prior to phase separation, a supplemental pH adjustment step to support biological inactivation to limit system and well fouling, and a review of necessary adsorption technologies (i.e., GAC, ion exchange) and residence times to achieve appropriate COC reductions in groundwater extracted for reinjection use. To facilitate implementation of the IRM within Site 114, the existing water treatment system will be relocated to a different portion of the Garfield Avenue Group (GAG) sites. As part of this relocation, any review or

retrofitting of the water treatment system will be performed to accommodate the conveyance and treatment needs for the IRM, achieving the same level of treatment previously observed to comply with permit specifications and treatment requirements. Supporting data for this review process will include historical data and analytical data collected as part of confirmatory sampling and baseline sampling activities following IRM well network installation.

### 3.1.4 Recirculation Conveyance and Reagent Mixing

The conveyance infrastructure for the Phase I system will be designed to facilitate adaptive extraction and injection operations, to allow flexibility for reuse of conveyance materials with different well sequencing, and to accommodate other site activities, such as earthwork and dewatering operations. A conceptual layout of the conveyance infrastructure is presented on **Figure 13**.

The water conveyance piping for the extraction wells will be standard dimension ratio (SDR) 11, high density polyethylene (HDPE) double-contained piping. The 2-inch carrier pipe and 4-inch containment pipe will readily accommodate the anticipated flow rates of 1 to 3 gpm. The individual extraction well conveyance line laterals will be joined conveyance header pipes, and those header pipes will be manifolded together at the system. The double containment will protect against leaks and prevent damage to the piping.

In addition to the extraction conveyance piping, 2-inch, non-metallic electrical conduits will be installed between each extraction well and the Phase 1 treatment system. Each extraction well will have two conduits, one for pump power wiring and the other for instrument signal wiring. The conduits will be installed alongside the conveyance piping to each well with adequate separation between the power and signal wire conduits to prevent interference. The conveyance piping and conduit for the extraction wells will be installed on land surface and protected with a temporary soil cover up to 3 feet deep, which both protects these utilities from damage and the elements and prevents water from freezing within the pipes. Buried utility runs will be marked with colored stakes at regular intervals as visual indicators. This conveyance piping and conduit installation approach will also be applied to those extraction wells that will be repurposed as injection wells at later phases of operation.

The treated water conveyance piping between the treatment system and each injection trailer will be a 2-inch SDR, 11 HDPE single-wall piping that will handle the anticipated 40 gpm maximum design flow for injection at each well field. Treated groundwater for reinjection will be routed to two mobile injection trailers staged in the southern part of Site 114. These trailers will include a storage tank for the stock reagent solution and appropriate metering pumps, in-line mixing components, and manifolding to control carbon substrate amendment into the treated groundwater prior to delivery into operating injection wells. Dynamic operation of these trailers will also be used to toggle between periods of carbon substrate pulsing and treated groundwater reinjection alone. These conveyance pipes will be manifolded at the system. Two-inch non-metallic electrical conduits will be installed between each injection trailer and the Phase 1 treatment system. Each trailer will have two conduits, one for power wiring and the other for instrument signal wiring. The conduits will be installed alongside the conveyance piping to each trailer with adequate separation between the power and signal wire conduits to prevent interference. Similar to the extraction well utilities, the injection trailer utilities will be buried and marked. The injection trailers will be centrally located at both injection well fields to minimize the need for trailer relocation.

Each injection trailer will be outfitted with an injection manifold and instrumentation to monitor and inject up to 10 injection wells at a time. Instrumentation will be installed at the injection manifolds to allow for pressure and flow monitoring for the active injection wells. Heat tracing and pipe insulation will be used to prevent the exposed pipes from freezing. Injection water will be conveyed to the active injection wells from the injection manifolds using flexible hosing that may be insulated and heat-traced, depending on the weather. Hoses will be placed on-grade, and hose runs will be marked using colored stakes at regular intervals as visual indicators.

If there is a need to move or alter the utilities to accommodate adaptive system operation, such as repurposing wells, or to accommodate other site activities, hoses, piping, and conduits can be uncovered and relocated or altered, as necessary. The use of flexible hoses, HDPE piping, and non-metallic conduit allows for flexibility in the utility layouts. Alternative methods of covering and protecting the lines will be considered during development of the final conveyance infrastructure design and may include burying portions of the delivery lines or using heat trace to eliminate freezing risk.

## 3.2 IRM Operation: Intermediate and Deep Water-Bearing Zones

### 3.2.1 Adaptive Management Overview

An integral component to successful groundwater recirculation remedies is maintaining an overall degree of adaptability over the course of operation to respond to field observations and to maintain the pace of overall remedial performance. Key aspects of the performance include Cr concentration reduction, mass recovery (extraction wells), organic carbon distribution, and evidence of reduced groundwater geochemical change within the subsurface. These indicators will be assessed as part of the Groundwater Monitoring Program (Section 5) and used to adapt overall extraction and injection operations during Phase I.

The conceptual layout for the IRM Phase I well network is provided on **Figure 10** and in **Appendix D**, which includes variable groups of injection wells that will be sequenced strategically over the course of the Phase I program to deliver both organic carbon and treated groundwater uniformly through the subsurface. Performance data will be used to guide system operation and unique well sequencing to meet the overall Phase I objectives over the course of operation. Data that will be evaluated continuously to optimize the remedial performance include, but is not limited to, the following:

- Monitoring well water quality data, including laboratory data (e.g., TOC, total Cr, and Cr[VI]) and field parameters (e.g., DO and ORP).
- Extraction well water quality data (e.g., TOC, total Cr, and Cr[VI]).
- Individual extraction and injection well flow rates.
- Treatment system influent water quality.
- Changes in overall Cr distribution extent and plume footprint.

The pulsing of carbon amendment in concert with the sequenced extraction scheme is key to overcoming aquifer heterogeneities, ambient hydraulic gradients, and preferred flow paths. Injections will be implemented gradually and stepwise from the southern portion toward the north. Continuous extraction

from the northern portion are intended to achieve mass removal, pull carbon amendment north, and balance the water demand required for injections. The specific timing of transitions between injection wells will be assessed based on the observations listed above. As the IRM Phase I progresses, specific adjustments (e.g., wells for extraction and injection, flow rates, organic carbon dosing) will be made to optimize the system performance. These adjustments will likewise be based on the observations listed above, and include the following:

- Increases and decreases in individual extraction well pumping rates to optimize mass recovery, distribute organic carbon, redox chemistry, and promote hydraulic control.
- Adjustments of individual injection well flow rates and duration of carbon amendment pulsing. This includes substrate dosing and volume adjustments to refine hydraulic control and optimize the distribution of organic carbon.
- Strategic conversion of extraction wells to injection wells or injection wells to extraction wells to optimize mass recovery, organic carbon distribution, and hydraulic control. This may also include the installation of additional extraction and/or injection wells.
- Strategic adjustments to the extraction scheme to ensure water chemistry and flow rate meets the treatment systems operational requirements.
- The type of organic carbon substrate (e.g., molasses and EVO) used and the relative dosing strength to induce and sustain the bioprecipitation processes in situ.
- The timing of organic carbon substrate dosing and recirculation shutdown and initiation of rebound monitoring.

The above management framework is advantageous in that it allows flexibility to provide a high likelihood of success and enables routine optimization for maximum Phase I efficiency. Each of these steps also serve to develop insights into supporting the transition of Phase I operations into subsequent phases of treatment at the GAG sites.

As reduction in Cr concentrations are achieved within the IRM Phase I area and attention turns to subsequent IRM treatment phases, select Phase I wells may continue to be operated as injection or extraction wells to maintain treatment performance during the transition. This will support hydraulic control, organic carbon distribution, and mass removal.

### 3.2.2 Reagent Selection and Dosing Strategy

In support of sustaining ISAB treatment mechanisms during active operation and post-IRM monitoring phases, multiple carbon substrates may be utilized. These will include dissolved-phase organic carbon materials (e.g., molasses) that can be easily distributed in the subsurface and longer lasting materials that can provide extended longevity following injection (e.g., EVO). Like other operational decisions, substrate selection will be an adaptive consideration with decisions based on field information obtained during IRM Phase I.

During system operation and injection, it is assumed that organic carbon will be dosed via the recirculation stream for approximately 4 hours per day. For the other 20 hours of daily operation, injection will continue to be treated with water but without substrate dosing. Dosing timing and reagent strength will

be supported by ongoing operational monitoring (Section 5) to strike an appropriate balance between sustaining overall injectability, limiting well fouling and potential back pressure generation related to fermented gas generation, and achieving subsurface TOC distribution.

A combination of ISAB substrates is considered for use during Phase I. Phase I operations will be initiated using molasses as the organic carbon substrate consistent with the previous ISAB pilot test. Over the course of operation, EVO will be considered during late stage recirculation to distribution a long-term source of organic carbon for supplemental post-operational polishing. While pulsed operation is anticipated, it is assumed for PBR approval purposes that the average organic carbon dosing over the course of the 12-month Phase I program is 0.5% by volume. Based on the projected total recirculation volume of 21 million gallons of groundwater, the organic carbon demands for Phase I will be no more than 105,000 gallons of substrate (either molasses, EVO, or a combination of both). As specified above, the actual dosing strength of these organic carbon substrates, the dosing durations per day (or per week), and the timing of molasses and EVO use will be determined based on monitoring observations.

Reagent flexibility is considered a key consideration for maximizing overall treatment during the IRM Program. While the carbon substrates above will serve as the primary reagents for use, other reagents are being included in this PBR to allow flexibility in the event that unique areas of the site are better suited to their application. As described in Section 2.2.2, both FerroBlack®-H and CaSx were used to achieve treatment during pilot test activities, and these reagents are retained for potential consideration during Phase I. CaSx could be delivered via the recirculation network as a soluble reagent for ISCR in select areas of Site 114 in lieu of or prior to use of carbon substrate. In addition to these two reagents, ferrous sulfate may also be used as a supplement to the carbon substrate source to provide additional iron and sulfide to further enhance Cr abiotic reduction mechanisms.

The Safety Data Sheets (SDS) for molasses, EVO, CaSx, and ferrous sulfate are included in **Appendix E**.

### 3.2.3 Injection and Extraction Well Flow Rates and Operating Sequencing

Consistent with the dynamic management approach discussed in Section 3.1.1 and **Appendix D**, operation of the individual injection and extraction wells will be modified based on routine performance data reviews reliant on both operational and treatment monitoring (Section 5) and updates to the dynamic groundwater and solute transport flow model. The sequencing of well operations are planned as part of three, 8-week steps to enable carbon distribution across the southern portion of Site 114 within the first 6 months. Supplemental operations would then be completed during the second 6 months to sustain treatment in areas requiring additional carbon delivery. Data collected over the course of operation will be used to adapt the overall program based on observed response, with a focus on overcoming aquifer heterogeneities and optimizing carbon amendment distribution. As a result, the individual steps or select operation of injection and extraction well locations may be modified from that proposed in Section 3.1.1 to accommodate hydrogeologic variability and the extent of distribution achieved.

Injection well operational sequencing steps and modification may include the following:

- Injection rates in individual injection wells may be reduced or temporarily stopped to alter the hydraulic gradients and stresses applied to the intermediate and deep aquifers. As previously

discussed, injection rates may also be reduced to focus available recirculation water on other well locations.

- The timing, duration, and dosing of carbon amendment pulsing may be adjusted to maximize sustainable flow rates and enhance carbon amendment distribution.
- Injection wells may temporarily or permanently be converted to extraction wells to enhance hydraulic control, mass removal, and/or overcome aquifer heterogeneities.

Similarly, individual extraction well operational modifications may include the following:

- Adjustment of extraction rates to optimize mass recovery, hydraulic control, overcome aquifer heterogeneities, and optimize carbon amendment distribution.
- Temporarily or permanently stop extraction. Groundwater extraction from an extraction well may be stopped if carbon amendment breakthrough is observed in the extraction well. Stopping extractions from the well will limit carbon loading of the treatment system and will prevent removal of the carbon substrate from the aquifer. In these instances, other extraction wells will be brought online to sustain the recirculation process and maintain overall recirculation water demands.

Injection wells positioned within the southern area of Site 114, which are not utilized as part of the initial operations, may be sampled as temporary monitoring wells to evaluate subsurface carbon distribution and to support decisions related to injection well sequence timing. Data from these wells may also be collected after injections have been completed to evaluate TOC longevity and to determine the timing of supplemental delivery, as necessary.

### 3.2.4 Well Development and Fouling Management

Arcadis' experience from similar groundwater recirculation and injection systems underpins the importance of a systematic well redevelopment and fouling management plan. This is particularly important for injection wells, where mixing of water with a range in redox potential and with organic carbon amendment can promote the formation of biofilms and/or metal precipitation. Biofilms and metal precipitation can be associated with a reduction in injection rates. A proactive injection well redevelopment scheme has been demonstrated to prolong good injection well performances at sites with similar remedy and geochemical conditions. Redevelopment may include physical scrubbing, surging, and jetting of the well with or without the addition of chemicals/pH adjustments to remove biofilm and metal precipitates. Initial concepts of well redevelopment and fouling management include redeveloping each injection well on a quarterly basis; however, consistent with the adaptive management plan, the schedule for redevelopment of certain wells may be adjusted based on operational data (e.g., observed injection flow rates and wellhead pressures).

### 3.2.5 Well Network Optimization

Additional or replacement wells may be installed as the IRM Phase I progresses. The wells may include both injection and extraction wells with the intent of:

- Replacing destroyed or severely fouled wells.

- Enhancing hydraulic control, Cr recovery, or carbon amendment distribution in areas where performance is observed to be limited.

Additional wells may also be added to increase the vertical distribution of amendment by targeting depth intervals not sufficiently addressed by the initial injection/extraction well network.

### 3.2.6 Waste Disposal

Soil cuttings and drilling mud generated from well installation will be containerized in properly labeled 55-gallon drums or larger containers and disposed of at an appropriate off-site disposal facility using existing investigation-derived waste (IDW) profiles for Site 114. Purged water from well development and groundwater sampling activities will be temporarily stored in tanks and transferred to the treatment system following sufficient time for solid to settle. The settled solids will be disposed of at an appropriate off-site disposal facility. Groundwater will be treated before being re-injected. Sludge or filter cake generated from this process will be disposed of at an appropriate off-site disposal facility.

# 4 PHASE I IRM DESIGN: SHALLOW WATER-BEARING ZONE

As discussed in the IRM Phase I program at the beginning of Section 3, shallow water-bearing zone polishing treatment for Cr-impacted groundwater will be implemented in the vicinity of the current water treatment plant and pilot testing areas located on the north-western portion of the site (**Figure 10**). This treatment is proposed to address an area of the shallow water-bearing zone that contains residual Cr impacts where excavation was completed but not amended with FerroBlack®-H. The shallow water-bearing zone treatment, proposed as part of this PBR, utilizes ISAB accomplished via carbon substrate injection via temporary injection wells.

The shallow treatment will be completed as part of one injection event using temporary injection points. Injection points will be placed throughout an area estimated to be approximately 20,000 square feet ($ft^2$). Additional refinement of the target treatment area will be supported by supplemental sampling activities performed as part of the Remedial Investigation Program prior to IRM implementation. This data will be integrated into data from pilot test wells, VAP sample locations, and other monitoring wells in the area to finalize the exact location and orientation of temporary injection points. Within this area, an estimated 70 total injection points will be installed on 20-foot on-center spacing. The estimated radius of influence from these locations is 10 feet, based on shallow water-bearing zone injection results observed during the ISAB pilot test.

Injection points will be installed prior to injection, utilizing direct-push drilling methods. Injection points will be constructed using 1-inch PVC casing materials and a 10-foot 0.020-slot injection screen. The screen interval will be placed at depths between 5 to 15 ft bgs or with a terminal depth consistent with the observed top of the meadow mat.

The selected carbon substrate for shallow water-bearing zone treatment is EVO, which provides extended organic carbon longevity following the one-time injection event. The injection solution will be mixed above-grade using temporary containment equipment to achieve an as-delivered EVO dosing rate of 2% by volume. Using the estimated mobile porosity of 14% determined during the ISAB pilot test (Arcadis 2017), a total volume of up to 235,000 gallons of 2% EVO solution and up to approximately 5,000 gallons of as-delivered EVO material will be injected within the target treatment area. Injection observations will be utilized to evaluate the total per-point injection volumes and make any necessary modifications based on feasible injection flow rates at each location. If select locations exhibit limited overall injectability, additional volumes may be delivered into adjacent points to optimize shallow water-bearing zone EVO distribution.

During injection, multiple injection points/piezometers will be manifolded together for simultaneous injection. Injection flow rates and pressures will be closely monitored and controlled to avoid any surfacing of reagents or fracturing of the formation. The SDS for EVO is included in **Appendix E**.

# 5 IRM MONITORING PROGRAM

The groundwater monitoring program for the IRM Phase I has been developed to support ongoing evaluation of Cr treatment effectiveness, to provide feedback related to Phase I recirculation operations, and to support continuous adaptation and optimization of the recirculation program. IRM Phase I monitoring activities are proposed as part of four primary categories to support treatment assessment and performance optimization. These consist of: 1) baseline sampling, 2) operational monitoring, 3) treatment monitoring, and 4) post-treatment monitoring.

A combination of both new and existing monitoring wells will be incorporated as part of each of these monitoring categories. A summary of the overall Phase I monitoring program is provided in **Table 3**, and a list of new and existing monitoring wells, included in each of these monitoring categories for the shallow, intermediate and deep water-bearing zones, are provided in **Table 2**. The monitoring well network is shown on **Figure 14**. In addition to these well locations, select Phase I extraction and injection wells may also be periodically added into the sampling program to supplement the dedicated monitoring well network locations.

The details of the groundwater monitoring program are discussed in the sections below.

## 5.1 Baseline Sampling

Prior to the startup of Phase I operations, but following the installation of the remediation well network and new monitoring well locations, samples will be collected for baseline analysis to establish the starting conditions for IRM treatment performance review. In accordance with **Table 3**, baseline samples will be collected for TAL metals (total and dissolved); Cr(VI) (total and dissolved); key geochemical parameters (sulfate/sulfide and methane); TOC, field parameters (pH, specific conductivity, DO, ORP, turbidity, and temperature); and depth to groundwater. A summary of the monitoring wells included in the baseline sampling event is provided in **Table 2** along with all the new injection and extraction wells.

Baseline samples will be collected using the low-flow sampling method. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 micrometer (µm) filters in the field.

## 5.2 Operational Monitoring

The operational monitoring program will be utilized to assess ongoing remedial system performance in support of guiding potential modifications to inject and extract flow rates, well balancing, carbon dosing and timing, and to pre-emptively guide potential biofouling management and well redevelopment. Operational monitoring will yield information pertaining to the sustainable recirculation flow rates, will confirm that wellhead injection pressures are within an appropriate range, will be useful in evaluating hydraulic influence of extraction and injection operations, and will confirm overall aboveground treatment system effectiveness in accordance with the WUR permit. Collectively, these data will be used to guide adaptive system operations, routine adjustments, and overall optimization.

Depending on the parameters, operational monitoring will be performed at variable frequencies (weekly, biweekly, or monthly), as necessary, over the course of operation (**Table 3**). A summary of the well locations included as part of the operational monitoring program is provided in **Table 2**. Measurements may be periodically performed more frequently than specified in **Table 3** to support potential troubleshooting activities over the course of operation. Given the adaptive nature of the recirculation program and the sequencing of different groupings of injection and extraction wells over the course of operation, it is anticipated that the operational sampling frequency of existing monitoring wells will be adapted over time. As an example, monitoring wells located within the southernmost area of Site 114 are most relevant for operational monitoring during the first step of recirculation activities. Following this initial 8-week period and the transition to more northerly injection wells, the frequency and parameter list of the initial monitoring locations may be reduced to maintain remedial efficiency, as applicable.

For the operational monitoring, analytical data and field parameter measurements for extracted and treated groundwater will be collected at operating extraction wells from sampling ports located at the wellheads or at the influent to the water treatment system. When collected from dedicated sampling ports, samples will be collected via grab sampling techniques. For individual well locations, samples will be collected using the one-volume purge sampling method (Arcadis 2017). The one-volume technique will entail dedicated tubing deployed to the middle of the screen intervals in each well for purging and sampling. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system.

## 5.3 Treatment Monitoring

Overall Phase I remedial performance will be documented via ongoing treatment monitoring over the course of the 12-month program. Sampling parameters will be collected to verify organic carbon distribution, assess the development of reduced geochemical groundwater conditions within the subsurface, and confirm corresponding declines in total Cr and Cr(VI). The development of the reactive zone confirmed via treatment monitoring activities will be used to guide carbon substrate dosing strength and frequency based on the observed subsurface response and confirm that reactive zone propagation has been achieved prior to transition of operating recirculation wells to subsequent steps. A summary of the analytical and field parameter measurements for treatment sampling is provided in **Table 3**, and well locations included in the overall treatment monitoring program are included in **Table 2** and **Figure 14**.

Similar to the operational monitoring specifications, treatment monitoring parameters will be collected at specified frequency based on the relevance of a given parameter to operation and optimization activities. TOC and field parameter sampling is proposed most frequently (biweekly to monthly) to effectively gauge propagation of both carbon substrate and geochemical influence within the subsurface. Total Cr and Cr(VI) and select geochemical parameters (ferrous [dissolved] iron, dissolved manganese, sulfate) will be collected monthly to enable the collection of at least one to two samples between recirculation well steps. Methane sampling is also proposed, albeit less frequently, to confirm the overall extent of reduced groundwater conditions. Similar to the sampling frequency considerations presented for the operational monitoring program, select well locations or parameters may be collected more frequently for system optimization purposes, as applicable.

Treatment monitoring samples will be collected using the low-flow sampling method. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment

system. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 micrometer (µm) filters in the field.

Data collected as part of the treatment monitoring program will be used to confirm treatment performance in areas undergoing active carbon recirculation and to confirm the longevity of TOC availability and treatment permanence as recirculation activities transition to other areas of Site 114. Data collected between recirculation cycles will also be used to determine whether subsequent carbon substrate delivery is required during the 12-month Phase I period. These decisions will be guided based on observed TOC strength, its longevity in the subsurface, and extent of observed Cr reduction.

## 5.4 Post-Treatment Monitoring

Following the 12-month Phase I operational program, post-treatment monitoring will be used to document overall Cr treatment performance, confirm the residual reactive zone reduction capacity (via residual TOC and reduced geochemistry species), and develop an appropriate data set to demonstrate ongoing natural attenuation of any residual total Cr and Cr(VI). Post-treatment sampling will be performed in accordance with **Table 3** and at well locations shown in **Table 2**.

Treatment monitoring samples will be collected using the low-flow sampling method. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system – or containerized and disposed of off-site, as appropriate. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 micrometer (µm) filters in the field.

Post-treatment sampling activities will be performed on a quarterly basis over a total duration of two years.

# 6 SCHEDULE AND REPORTING

Details of the supplemental pre-design testing, well and system installation, system operation, and performance monitoring results associated with the IRM Phase I program will be documented as part of a quarterly technical status reports submitted to the NJDEP. These quarterly status reports will include succinct, high-level summaries of activities performed, data collected, adaptive steps taken to modify or optimize Phase I treatment, and an overview of activities planned for the subsequent quarter.

Upon approval of this IRM Phase I Work Plan and the PBR Authorization by NJDEP and receiving all the applicable permits required to conduct the field work detailed in this design, PPG proceed with startup of the IRM Phase I program. As detailed in Section 2.5, confirmatory testing activities in support of design finalization are planned concurrent with NJDEP review, with these data being utilized to advance specific design elements and refine the hydraulic understanding in select areas of Site 114. Other IRM infrastructure construction (e.g., well installation, water treatment plant modification, conveyance piping installation) may also be initiated prior to final approval to expedite elements of the project schedule, as necessary. The IRM Phase I operation is anticipated to start in fourth quarter of 2017 and last for a duration of up to approximately 12 months, followed by a post-operational monitoring of 2 years. As-built layouts for the IRM Design will be provided as part of the first quarterly status report, anticipated during first quarter 2018.

The schedule for implementation of the IRM Phase I program may be adjusted based on regulatory review and approval of the PBR Authorization and the Work Plan.

**Table 3**
**IRM Phase I Groundwater Monitoring Program**
**Groundwater IRM Phase I Design and PBR Authorization Request**
**PPG Garfield Avenue Group Sites, Jersey City, New Jersey**

| Monitoring Program | Monitoring Well Network | Monitoring Parameters | Monitoring Frequency |
|---|---|---|---|
| Baseline Monitoring | New extraction, injection, monitoring wells and existing monitoring wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature<br>2. **Lab Analytical**: Total/dissolved TAL metals, total/dissolved Cr(VI), TOC, sulfate/sulfide, and methane | Prior to operation start |
| Operational Monitoring | New extraction and monitoring wells, existing shallow, intermediate and deep monitoring wells, and system sampling port (influent and effluent) | 1. **Field Parameters**: DTW | Weekly - Biweekly |
| | | 2. **System Parameters**<br>- Injection / extraction well flow rates | Weekly |
| | | - Wellhead pressures | Weekly |
| | | - Water treatment system monitoring | Weekly - Monthly (as appropriate) |
| Treatment Monitoring | New extraction and monitoring wells, and existing intermediate and deep monitoring wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature | Biweekly - Monthly |
| | | **2. Lab Analytical:**<br>- Total/dissolved Cr and Cr(VI) | Monthly |
| | | - TOC | Biweekly - Monthly |
| | | - Supplemental geochemical parameters (sulfate, ferrous [dissolved] iron, dissolved manganese) | Monthly |
| | | - Methane | Monthly - Quarterly |
| Post-Treatment Monitoring | New monitoring wells and existing shallow, intermediate and deep monitoring wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature<br>2. **Lab Analytical**: Total/dissolved TAL metals, total/dissolved Cr and Cr(VI), VOCs, SVOCs, TOC, sulfate/sulfide, dissolved iron, dissolved manganese, and methane. | Quarterly following system shutdown for up to 2 years |

**Notes:**

1. The monitoring locations, parameters, and frequencies provided in this table serve as a general guidance for IRM-related monitoring activities and may be adjusted or changed based on IRM Phase I performance, injection and extraction areas in operation, and observed monitoring results.
2. Dissolved metal samples are to be field filtered prior to sample collection.

Cr - chromium
Cr(VI) - hexavalent chromium
DO - dissolved oxygen
DTW - depth-to-water
IRM - Interim Remedial Measures
ORP - oxidation-reduction potential
PBR - Permit-by-Rule
SVOCs - semi-volatile organic compounds
TAL - target analyte list
TOC - total organic carbon
VOCs - volatile organic compounds

# APPENDIX A

## Draft Public Notice

## DRAFT PUBLIC NOTICE

Take notice that, as part of the remediation of Garfield Avenue Site 114 and Former Halladay Street Gas Works at 900 Garfield Avenue, Block: 21501 Lots: 16,17,18, 19, 20, in City of Jersey City, Hudson County, a proposal has been submitted to the New Jersey Department of Environmental Protection (Department) to discharge to ground water in accordance with a permit issued pursuant to the provisions of the New Jersey Water Pollution Control Act, N.J.S.A. 58:10A-1 et seq., the New Jersey Pollutant Discharge Elimination System, N.J.A.C. 7:14A; the Ground Water Quality Standards, N.J.A.C. 7:9C; and the Technical Requirements for Site Remediation, N.J.A.C. 7:26E. The Department's Site Remediation Program is reviewing the proposal to discharge to ground water for the purpose of remediating a contaminated site with the program interest # G000008791.

Brief description of the proposed discharge: The Phase I pilot study will be implemented at Site 114, which is located at 900 Garfield Avenue in Jersey City, Hudson County, New Jersey. The site is located on the Jersey City peninsula approximately midway between the Passaic River and Hackensack River junction to the west (approximately 1.8 miles) and the upper bay/mouth of the Hudson River to the east (approximately 1.6 miles). The local overburden geology is generally consistent with the regional geologic mapping, and includes approximately 16 feet of poorly sorted fill materials over organic rich meadow mat. The meadow mat occurs over most of the site and marks the transition from the shallow fill aquifer to the intermediate depth and deep aquifers, although in some areas the meadow mat is absent. The Pilot Study will include a combination of groundwater extraction, treatment, and reinjection to achieve in-situ anaerobic bioprecipitation (ISAB) and in-situ chemical reduction (ISCR) In the overburden. ISAB will be achieved by injecting organic carbon substrate (e.g., molasses and/or emulsified vegetable oil [EVO]) to establish geochemical reducing conditions to stimulate native microbial community for reducing hexavalent chromium (Cr[VI]) to trivalent chromium (Cr[III]) which will eventually be precipitated and permanently fixed in soil formation. At the same time, distribution of injected organic carbon substrate and expansion of established reducing conditions (ISCR) will be supported with a dynamically operated well network (i.e., alternately operating wells for extraction and/or injection as needed) and groundwater recirculation (i.e., reinjecting of extracted groundwater after aboveground treatment). A copy of this public notice has been sent to the Municipal Clerk and designated local health official for Jersey City and Hudson County.

A copy of the discharge to ground water proposal is available from the person responsible for conducting the remediation (Mark Terril, One PPG Place, Pittsburgh, PA 15222), or as part of the administrative record which is on file at the offices of the Department, Site Remediation Program, located at 401 East State Street, Trenton, Mercer County, New Jersey. The file may be reviewed under the New Jersey Open Public Records Act (OPRA), N.J.S.A. 47:1A-1 et seq. Information regarding the OPRA procedures is available at http://www.state.nj.us/dep/opra/oprainfo.html.

Interested persons may submit written comments regarding the discharge to ground water proposal to the Department at the address listed below and to the owner or operator of the facility: Richard Feinberg, 900 Garfield Avenue, Jersey City, NJ, 07305. All comments shall be submitted within 30 calendar days after the date of this public notice, or the end of any public hearing that the Department may schedule that occurs after that date. All persons who believe that the discharge to ground water proposal is inappropriate, must submit all reasonably ascertainable issues in writing to the Department, with all

supporting material, by the close of the public comment period. The Department will consider all public comments that relate to the discharge to ground water proposal, provided that the Department receives the comments by the close of the public comment period. After the close of the public comment period, the Department will render a decision regarding the proposed discharge to ground water.

The Department will respond to all significant and timely comments with its decision regarding the discharge to ground water proposal. Each person who has submitted written comments will receive notice of the Department's decision.

Any person may request in writing that the Department hold a non-adversarial public hearing on the discharge to ground water proposal. This request shall state the nature of the issues to be raised in the proposed hearing and shall be submitted within 30 calendar days of the date of this public notice to the address cited below. A public hearing will be conducted whenever the Department determines that there is a significant degree of public interest in the discharge to ground water decision. If a public hearing is held, the public comment period in this notice shall automatically be extended to the close of the public hearing.

Comments and written requests for a non-adversarial public hearing shall be sent to:
