**Appendix B-2**
**Summary of Historical Soil Sample Analytical Results**

| Lab Qualifiers | Definition |
|---|---|
| * | Laboratory duplicate analysis was outside control limits. |
| B | Indicates an estimated value between the instrument detection limit and the Reporting Limit (RL). |
| E | Serial dilution results not within 10%. Applicable only if analyte concentration is at least 50X the IDL in original sample. |
| J | Indicates an estimated value. |
| N | Spike sample recovery not within control limits. |
| R | Rejected. |
| U | The compound was analyzed for but not detected. The associated value is the compound quantitation limit. |

**Notes:**
**Bold indicates parameter is detected above Reporting Limit**.
% = percent.
$H_2$ - hydrogen.
meq/100g = milliequivalents per 100 grams.
mg/kg = milligrams per kilogram.
mV = millivolts.
NA = not analyzed.
S.U. = Standard Units.
(a) Calculated as: (iron) - (iron, ferrous).
(b) Calculated as: (nitrogen, nitrate + nitrite) - (nitrogen, nitrite).
(c) The ferrous iron test was analyzed after completion fo hexavalent chromium testing (outside of normal hold times for this parameter) in order to provide more information about the possible impact of the sample matrix on hexavalent chromium recoveries.
(d) Thesulfide screen was analyzed after completion fo hexavalent chromium testing (outside of normal hold times for this parameter) in order to provide more information about the possible impact of the sample matrix on hexavalent chromium recoveries.

## I. Test Design

In general conventional hydraulic testing is conducted to provide answers to questions related to water supply problems. Tests are conducted over longer periods of time and provide estimates of hydraulic conductivity values averaged over large aquifer volumes. These tests tend to underestimate the highest hydraulic conductivity values and overestimate the lowest.

When conducting tests for remediation hydrogeology purposes it is important to indentify aquifer heterogeneities which ultimately control the transport of contaminants and reagents distribution within the aquifer. Short-term tests may help identify particular depositional elements and hydraulic conductivity trends and variability associated with facies changes in the aquifer. Data collected from short-term test can then be correlated with detailed hydrostratigraphic information to assist in the development of conceptual site models that describe the transport of contaminants and distribution of reagents.

### 1. Understand Aquifer Conditions

An aquifer (or permeable zone) pumping test is conducted in order to determine the hydraulic properties (transmissivity, hydraulic conductivity, storage coefficient, leakage, boundaries, anisotropy) of a water-bearing zone or system (including confining beds). Proper design of a pumping test requires a general understanding of the potential hydrologic system prior to the test, so that suitable data are collected to evaluate system parameters. The designer of the test must first develop an appropriate set of assumptions (conceptual model), either taken from previous tests in the immediate area or from well logs and an assessment of the site features that can affect the test (soil or rock types, depth to water, surface- water bodies, existing wells, storm drains). This conceptual model will then help the designer anticipate the necessary design factors such as: number of wells, depth and placement of wells; pumping rate(s); frequency of water-level measurements; and length of pumping. These factors will help the designer determine from the test results the effects of recharge and restrictive boundaries, aquifer geometry, secondary porosity effects (fractures, solution channels), the nature and extent of potentially confining layers, and aquifer interconnections.

### 2. Estimate Aquifer Parameters

Although the objective of a pumping test is to determine the principal aquifer parameters, the conceptual model requires a prediction of some of these parameters for the design process (i.e., observation well number and spacing requires approximate transmissivity and storage coefficient values). Hydraulic conductivity may be estimated from textural or hydraulic testing of aquifer materials in the laboratory, or from data collected and observations made during drilling or well development (see Driscoll, 1986). Considerable experience is needed to apply these methods for anything but preliminary estimating purposes. Therefore, use as many approaches

as possible when making these estimates and remember that they are only estimates. Be ready to adjust preliminary estimates as more information becomes available throughout the process.

For larger tests (and thus larger pumping wells), potential casing storage effects and well (friction and formation) loss may need to be calculated prior to the test. Also, optimum pump size may need to be calculated. These will require an estimate of specific capacity, which is the well discharge rate per unit of drawdown measured at a given time. Specific capacity is typically determined from a step-drawdown test. An added benefit to conducting a step-drawdown test is the graphical results can also be used to calculate transmissivity (but not storage coefficient) in addition to well losses (see Section B.9).

**3. Locate the Pumped Well**

At many sites, the pumping well location is predetermined because an existing well suits the needs of the test, or the hydraulic properties of a specific location must be measured. If the pumping well location can be selected with relative freedom, the following criteria can be used as a guide for its installation:

a) where the hydrogeology represents the area of interest;

b) proximity to existing wells that could be used as observation wells (see guidelines 5, 6 and 7 below);

c) within the targeted contaminant plume whenever possible;

d) outside the contaminant plume if the system is areally homogeneous (or nearly so) and pumping of contaminated water poses an insurmountable problem;

e) away from groundwater system boundaries (assuming their approximate position is known) when the test purpose is solely to measure aquifer storage and transmission properties;

f) close to groundwater system boundaries (assuming their approximate position is known) when requiring boundary location, orientation (both positive and negative boundaries), or degree of connection (positive boundaries);

g) away from surface features that could obscure the data (for example, surface-water bodies) and away from areas subject to heavy-equipment traffic (i.e., railways and highways) that would put unpredictable stress on the aquifer, unless desiring specific information about the interrelationship of the groundwater system and surface features;

h) away from other producing wells that may not be shut down and may affect test data; and

i) where the site is safely and easily accessible to equipment and personnel.

Although these guidelines generally support test success, strictly adhering to them may produce conflicting test designs. Resolving these design conflicts requires good judgment based on a clear understanding of the test priorities and an appropriate knowledge of the local groundwater system.

**4. Design the Pumped Well**

a) The casing must accommodate the pump used for the test and allow ample additional space for measuring equipment.

b) The pumped well should be as efficient as possible through sound drilling practices, installation, and construction. A wire-wrapped screen and site-specific filter pack, designed from a sieve analysis, should be used to reduce factors that will mask true aquifer response.

c) If possible, a stilling pipe should be installed in the pumped well for making water- level measurements. The stilling pipe will dampen water-level fluctuations caused by pump vibration, eliminate measurement errors associated with cascading water, and isolate pressure transducers from pressure transients near the pump intake.

d) Generally, the screen in the pumped well should fully penetrate the tested zone to eliminate the complicated data analysis and interpretation required to correct for partial penetration effects (induced vertical flow component in addition to radial flow), with the following two exceptions:

   1) if the screen would form a conduit capable of transmitting chemicals from a contaminated horizon to a clean horizon; or

   2) when attempting to determine an aquifer's vertical anisotropy (ratio of vertical to horizontal hydraulic conductivity). This determination is necessary if remediation well capture zones will not affect the full thickness of the aquifer.

For these two conditions, the pumped well should only penetrate the contaminated portion of the aquifer. In addition, cost considerations may limit full penetration of the tested zone.

e) The pumped well must be fully developed to maximize the pumping rate from wells with limited available drawdown, simplify data interpretation and assure that no additional development occurs during the test.

f) Often, pumping wells are later used as monitoring or recovery wells. Such wells should be designed according to the requirements of the particular application without compromising the aforementioned standards for pumped wells.

**5. Determine the Number of Observation Wells**

Observation wells help quantify the size, shape, position, and rate of change of the cone of depression formed by pumping, making it possible to determine aquifer parameters. Adding wells increases the amount and accuracy of information acquired, and improves confidence in the data. The number of observation wells selected, however, must balance the information needs with the cost of constructing them.

Without observation wells, only transient analysis (time-drawdown) methods may be used to determine aquifer properties, and only transmissivity and hydraulic conductivity can be determined. A single observation well makes it possible to determine storage coefficient, but data analysis is still restricted to transient methods. Two or more observation wells permit the use of distance-drawdown methods of analysis, greatly improving the accuracy of aquifer parameter estimates. Distance-drawdown analysis is especially important whenever transient analysis methods are apt to produce erroneous results, as often occurs in unconfined aquifers, tight sediments, leaky aquifers, and aquifers with boundaries near the pumped well. Therefore, when possible, use at least two observation wells during a pumping test. Determining parameters such as leakage/delayed yield and anisotropy usually require more than two observation wells.

**6. Design the Observation Wells**

a) The observation well diameter must be large enough to accommodate instrumentation used to measure water levels and small enough that the volume of water in the well does not cause a time lag in responding to aquifer drawdown changes.

b) Unlike the pumped well, observation wells need not be highly efficient, just open enough to reflect pressure changes that occur in the aquifer. Thus, inexpensive construction materials such as slotted screens may be used (unless they will be used later as monitoring, recovery, or injection wells). Yet, to accurately represent the potentiometric changes that may differ vertically in the aquifer, the well intake must be open to the aquifer from top to bottom. This objective can be achieved with moderate well development. Techniques such as surging and bailing, which provide modestly effective development, can be used.

c) Generally, observation well screens should be fully penetrating to eliminate complications in data interpretation caused by partial penetration. As with the pumping well, the exceptions to this rule are:

    1) Avoid fully penetrating screens where they would create a conduit capable of spreading contamination;

2) Use short screens to assess vertical anisotropy at discrete elevations in the aquifer.

Short screens are appropriate for observation wells installed in aquitards that are being used to assess connectivity, recharge, or delayed yield factors.

As stated above, fully penetrating wells will simplify the data analysis because hydraulic theory for fully penetrating systems is simpler than that for partially penetrating ones. Theory also predicts that, for a confined aquifer, an observation well will show fully penetrating response if either it or the pumped well is fully penetrating. That is, in theory, both need not be fully penetrating --it is sufficient that just one or the other be fully penetrating to observe the simplified fully-penetrating response. In practice, however, it is preferable that both the pumped well and the observation well be fully penetrating, if possible. In aquifers where hydraulic conductivity varies substantially with depth, it is possible that a fully penetrating response would not actually occur unless both the pumped well and observation well were fully penetrating.

**7. Situate the Observation Wells**

a) Lateral Distribution

When using two observation wells, they should be positioned along a straight line radiating from the well. Accurately assessing horizontal anisotropy or near-well boundaries requires three pairs or sets of observation wells positioned along three different lines emanating from the well. If the principal axis of anisotropy is known, two sets of observation wells will suffice, one along the principal direction of anisotropy and one perpendicular to it. For example, if a fractured rock aquifer is known to be more permeable north-south than east-west, one set of two or more observation wells would be installed on a line north (or south) of the pumped well and another set along a line east (or west) of the pumped well.

In theory, single wells placed on three different lines emanating from the pumped well are sufficient to assess horizontal anisotropy. In practice, however, other heterogeneities can influence drawdown readings enough to bias the calculated anisotropy if just a single well is used along each line. Therefore, it is preferable to use pairs of wells whenever possible.

b) Well Spacing

Observation wells along a particular line from the pumped well should be spaced logarithmically with the distance to each successive observation well approximately double that to the preceding well. For example, three observation wells may be placed at distances of 10 ft, 20 ft, and 40 ft from the pumped well, or 50 ft, 100 ft, and 200 ft from the pumped well.

There are advantages and disadvantages to locating observation wells either near to, or far from, the pumped well. Distance drawdown analysis methods tend to integrate aquifer properties over the area spanned by the observation wells, so distant wells tend to yield aquifer parameters representative of a broad area of aquifer. At great distances, however, wells may exhibit drawdowns so small that they are difficult to measure accurately or analyze confidently. On the other hand, observation wells installed near the pumped well show more substantial drawdown but tend to reveal aquifer properties on a smaller scale. Situating observation wells, therefore, depends on the type of information required. For contamination investigations of small plumes, closely spaced observation wells provide satisfactory data.

The data set will be more reliable if substantial drawdowns can be attained in the observation wells. This is accomplished by maximizing the flow rate and locating the observation wells sufficiently close to the pumped well. As a rule of thumb, the distance from the pumped well to the nearest observation well should not exceed the square root of the expected radius of influence of the pumped well. R can be determined from:

$$R = \sqrt{\frac{0.04Tt}{S}}$$

where

R = radius of influence in ft

T = estimated transmissivity in $ft^2$/day

t = pumping test duration in days

S = storage coefficient

For example, in tight sediments, if the expected radius of influence is less than 100 ft, at least one observation well should be located within 10ft of the pumped well.

Be aware that the oft-repeated recommendation to locate the nearest observation well one or two aquifer thicknesses from the pumped well is actually a generalization (not entirely correct) for locating partially-penetrating observation wells away from a partially-penetrating pumping well. The actual radial distance for a partially-penetrating observation well must take into account anisotropy, as follows:

$$r = \frac{1.5b}{\sqrt{\frac{K_z}{K_{xy}}}}$$

where

r = radius from pumping well

b = thickness of aquifer

$K_z$ = vertical hydraulic conductivity

$K_{xy}$ = horizontal hydraulic conductivity

In most instances, and especially in unconfined or tight sediments, use closely spaced observation wells and eliminate partial penetration effects by using fully penetrating wells, or compensate for partial penetration effects by determining the anisotropy of the aquifer.

c) Vertical Distribution of Observation Wells

Generally, make sure that observation well screens are located in the pumped aquifer and fully penetrate it. To determine vertical anisotropy, however, screens must only partially penetrate the aquifer. For this determination, install observation wells in pairs at the same location, with one well screened in the pumped interval and the other screened in an unpumped interval of the aquifer to get a three-dimensional view of the pressure reductions caused by pumping.

If pumping is expected to induce leakage across an aquitard and if the leakance must be determined, place one or two piezometers in the aquitard to assess the magnitude of the drawdown, if any, created by the pumped well. Aquitard-monitoring wells should have short screens approximately centered in the aquitard, to keep the screen as far as possible from the top and bottom of the aquitard. Ideally, an aquitard observation well should be drilled at the same location as an observation well completed in the pumped aquifer.

**8. Establish the Pumping Test Duration**

a) The duration of pumping tests can range from a few hours to a few weeks depending upon the nature of the formation and the type of information required. For example, in highly transmissive confined sediments, if only near-well transmissivity must be known, a 2-hour test might suffice. However, to acquire information about boundaries or leakage, or if sediments are tight or unconfined, a much longer test is required. The preliminary test of the pumped well (Section B.9) will help in planning the test length.

b) For confined aquifers, a test duration of 24 to 48 hours will generally provide the information required.

c) Longer tests are required for unconfined aquifers because the cone of depression expands more slowly and delayed-drainage effects retard the response of the aquifer to pumping. Plan to conduct pumping tests in unconfined aquifers for 3 days or longer.

d) If leakage effects among aquifers must be determined, a longer test is appropriate. For example, under confined conditions, it may be desirable to extend the test to two or three days.

e) Economics may dictate curtailing the length of the pumping test if treating or storing pumped water is expensive. If water disposal is inexpensive, however, it makes sense to extend the test because the cost of the additional pumping and monitoring required is generally nominal.

**9. Select the Appropriate Flow Rate and Measurement Device**

a) The objective of the pumping test is to stress the aquifer sufficiently to obtain a meaningful, measurable response. Generally, the magnitude of the drawdown response in most observation wells is small. Thus, in most aquifer tests, design the well and pump intake in such a way that a sufficient stress is placed on the aquifer system that can be measured at a distance.

b) Select the pumping rate on the basis of a preliminary test (such as a step-drawdown test, Section B.9) so that the rate can be sustained by the pump for the duration of the test. The rate should not be so large that the water level is drawn down into the screen area, causing cascading effects and entrained air; under no circumstances should the water level be drawn down to the water entry of the pump or tail pipe.

c) Small variations in the discharge rate create large errors in the calculation of aquifer parameters. Therefore, sustaining a constant discharge rate is more important than knowing the exact rate with great accuracy. Accordingly, maintain the flow rate as closely as practical to a constant value, usually within $\pm$1 percent or less. This can be achieved only if the flow rate can be measured precisely and adjusted easily as needed.

d) Always operate the pump against a partially closed valve so that, as drawdown increases during the test, a compensating reduction in back pressure is achieved by gradually opening the valve. The correct valve and flow measurement method are critical to this requirement. Select a valve that can be opened or closed in tiny increments to ease flow-rate control. A ball valve that opens fully or closes fully with a single 90-degree turn of a handle is undesirable because careful adjustments are difficult to achieve. A better choice is a gate valve that requires several 360-degree turns to open or close.

e) Flow measurement devices are typically based on three principles; head-type (orifice, venturi), velocity-type (magnetic, ultrasonic), and displacement-type (rotor, paddlewheel). Measurement devices/methods for a pumping test, in order of preference, are as follows:

1) Orifice weir with manometer (see Driscoll, pg 537): This is the best method of measuring the flow rate because it is precise, allows instantaneous reading of the flow rate so that adjustments can be made readily, and is relatively "low-tech". While most orifice weirs accommodate higher flow rates, small-scale versions can be made for flows as small as a few gallons per minute. Such custom-made meters can be calibrated easily in the field with a bucket and stop watch. Installing a totalizing meter in line with and upstream from the orifice weir provides assurance that the total discharge for the test is calculated accurately. After completing the test, total discharge volume is divided by test duration to determine average flow rate.

2) Instantaneous (ultrasonic) flow meter: non-invasive, can be equipped with a data logger. Some meters may not respond properly when pumping sediment-laden water or two-phase fluids like hydrocarbons and water.

3) Paddlewheel totalizing meter: shows total volume pumped. When using this type of meter, flow rate must be determined by taking consecutive readings and dividing by the time between them. Accuracy may vary from one meter to another. Also may not respond properly when pumping sediment-laden water or two-phase fluids. Meter inaccuracy at low flow rates can be allayed by installing a flow restrictor (such as manufactured by Clack Corporation) upstream of the meter. The restrictor creates enough back pressure on the pumping unit to minimize flow rate fluctuations.

4) Bucket, or other container of known volume, and stop watch. For low flows, this procedure is about as accurate as any for determining the flow rate. It also serves as a reliable calibration tool for other flow measurement devices.

Other methods of measuring flow rate involve using various types of weirs, flumes, and open-discharge pipes generally do not provide the precision required for controlling the flow rate during a constant-rate pumping test.

**10. Select the Pump**

a) The pump used must have sufficient capacity to maintain the required discharge throughout the constant-rate portion of the test and to produce the various flow rates required for the step-drawdown test.

b) The pump should be capable of delivering the planned discharge rate at pressures substantially higher than the apparent nominal pressure required to lift water to the surface and overcome friction losses in the piping system. Pumping against a high head such as 60 to 100 psi tends to reduce discharge rate variations. It also permits operating the pump against a partially closed valve, creating additional head to help minimize flow-rate fluctuations during the test.

c) Submersible or turbine pumps driven by electric motors are ideal for conducting pumping tests because (barring spikes or storms) they run at nearly constant rates, producing generally uniform flow. Turbine pumps driven by gasoline or diesel engines, however, cause greater flow-rate variations because engine output can vary with fuel mixture, and air temperature and pressure.

d) The pump should be equipped with a check valve so that water in the column pipe and discharge pipes doesn't siphon back into the well following pump shut off. This prevents a sudden charge of water from obscuring the early recovery data and making analysis more difficult.

**11. Plan for Pumped Water Disposal**

a) Discharge pumped water so that pumped aquifer zones are not recharged. To accomplish this, pipe water to nearby storm or sanitary sewers, or lined surface-water bodies. If these options are not available, arrange to spread the discharge water on the ground sufficiently far from the pumping test site so that infiltration will not affect the test results.

b) If the water quality is such that direct discharge is not permitted, treatment may be necessary. Occasionally, water treatment facilities are already available on site. Alternatively, it may be possible to arrange for temporary treatment equipment just for the pumping test. If disposal during the test is not possible, the fluid can be discharged to containers such as frac tanks temporarily. Provisions must be made for the appropriate number and size of containers to handle the volume of water pumped during well development, step-drawdown testing, and constant-rate testing, plus a safety margin.

c) Discharge water must be disposed according to all applicable laws and regu1ations. Contact the governing agencies to determine which restrictions apply.

d) ARCADIS should not be responsible for signing manifests and should not "take possession" of discharged water.

**12. Check for Casing Storage**

Casing storage effects will render useless the early time/drawdown data from pumping tests. The larger the well diameter and the lower the specific capacity, the longer casing storage effects persist. Data recorded before casing storage effects end (at $t_c$) cannot be analyzed by any method.

The duration of the casing-storage affected portion of the test can be estimated as follows:

$$t_c = \frac{0.6\left(D^2 - d^2\right)}{Q/s}$$

where

$t_c$ = duration of casing storage effect ('critical time'), in minutes

D = inside diameter of well casing, in inches

d = outside diameter of pump column pipe, in inches

Q = flow rate, in gpm

s = expected drawdown in the pumped well, in ft

Before conducting the test, it is important to estimate $t_c$. If the value is large, take steps to minimize storage effects if possible. For example, a packer may be installed with the pump column pipe to keep the water standing in the well casing from being removed from the well. If this is done, the packer must be specially designed to permit measurement of the hydraulic pressure in the well just under the packer. Alternatively, it may be possible to install ballast material alongside the column pipe to take up space and reduce the volume of water stored in the casing. For example, a 3.5-inch OD PVC pipe run alongside the column pipe in a low-yielding, 4-inch well, can reduce the duration of casing storage effects by 75 percent.

To demonstrate the significance of casing storage, a 4-inch test well in tight sediments with 1.25-inch column pipe producing 2 gpm with 30 ft of drawdown results in the following calculation:

$$t_c = \frac{0.6\left(4.026^2 - 1.66^2\right)}{2/30}$$

= 121 minutes

Thus, the first two hours of test data from this well cannot be analyzed.

In filter-packed wells, if water in the filter pack can drain quickly into the well (such as in wells that are screened across the water table), the equation for $t_c$ must be modified to account for filter pack storage. The accomplish this, the term

$$D^2 - d^2$$

is replaced by

$$\left(D^2 - d^2\right) + S_y\left(B_d{}^2 - C_d{}^2\right)$$

where

$B_d$ = diameter of borehole, in inches

$C_d$ = outside diameter of casing, in inches

$S_y$ = short-term specific yield of filter pack material --approximately 0.1 or 0.15

## II. Pretest Activities

a) Unless installed specifically for the test, sound all wells for use in the test to verify well depth. (Do not use water level meters for this purpose, because some meters have probes that leak and trap water when subjected to excessive pressure.) Also, if adequate connection to the aquifer is suspect, conduct a slug test (either 'in' or 'out' - attempt to change the water level by at least 2 feet) in the observation wells. If the water-level response is too sluggish or no response is apparent, redevelop the well.

b) Label all wells (temporarily, if necessary) for quick and easy identification throughout the test.

c) Unless previously verified, measure the distance of all observation wells from the pumping well to the nearest foot.

### 2. Select Appropriate Water Level Measuring Devices

a) Pressure Transducers and Data Logger Combination

Transducers connected to electronic data loggers provide rapid water-level measurements with accuracy and ease. Some electronic data loggers (i.e.,

Hermit) collect and store data from a number of input channels (downhole pressure transducers plus atmospheric pressure) to provide water-level measurements in multiple within several hundred feet radius of the data logger, while others consist of a single logging transducer (i.e., Troll™, Levelogger™). Typical loggers take readings at preprogrammed linear or logarithmic intervals. If desired, data can be transferred to a personal computer for processing.

Small-diameter transducers (typically 0.5 to 0.75 in) are available that cover a range of pressures. Because they yield readings accurate to a percentage of their pressure range (usually about ±0.1 percent of the range in the center of that range, and ±0.2 percent near the limits) transducers that span a wide pressure range have lower absolute accuracies than those that span a narrow range. For example, a typical transducer with a 5 psi range detects water-level changes over a 11.6 ft with an accuracy of ±0.01 ft, whereas, a transducer with a 15 psi range detects changes over a 34.7 ft with an accuracy of ±0.03 ft. Thus, to ensure the greatest accuracy, select the transducer with the pressure range that most closely encompasses the anticipated drawdown or water-level change. Furthermore, confirm transducer water-level measurements throughout a test by manually taking regular water-level readings with a water level meter.

Caution: To prevent transducer malfunction, do not submerge transducers in excess of their operating range.

b) Water Level Meters, Interface Probes

These devices provide quick and easy water-level measurements with reasonable accuracy. They employ a sensor that is lowered into a well on the end of a marked cable (typically imprinted in feet and hundredths of a foot). When the sensor contacts water, a circuit is completed, activating a light, audio signal, ammeter, or digital display in the cable reel or housing. However, because the measurements are manual, the speed of readings cannot match those of a pressure transducer with a data logger. Thus, a water level meter is most useful in taking correlative, manual measurements in wells as a backup and for data checking, as well as measuring wells outside the active observation well network.

When appropriate, one water level meter should be used to take readings in all wells. If more than one meter is used to make site-wide water-level measurements, record the serial numbers and make comparison measurements within a single well to calibrate to a common standard.

c) Wetted Steel Tape

When using a steel tape, attach a weight to the bottom, wipe dry and coat the lower 2 to 3 feet with carpenter's chalk or water-soluble ink from a felt-tip marker, lower the tape into the well until part of the coated section extends below the water level, hold one of the major division (e.g., foot) markings at the predetermined measuring point, and record this reading. After withdrawal, read the wetted line on the coated section to the nearest 0.01 ft. Subtract this reading from the mark held at the measuring point; the difference is the actual depth to water.

A wetted steel tape is accurate and reliable, and is useful to verify and calibrate readings from other instruments. The procedure, however, is more time-consuming than others, limiting its usefulness during the early portion of pumping test when many rapid measurements are required. Furthermore, the approximate depth to water must be known in advance to ensure that part of the chalked section is submerged to produce the wetted line.

**3. Verify Measuring Device Accuracy**

Test pressure transducers and data logger readings using a bucket or barrel filled with water. Submerge each transducer, accurately measure the water head above the transducer, and compare the measurement to the data-logger reading. Check transducer response to changing heads by raising the transducer a certain distance, observing the change in the datalogger reading, and then measuring the distance with a standard steel tape. Water level meters should be in good working condition and calibrated, ensuring there are no breaks or splices in the cable.

**4. Establish a Reference Point for Measuring Water Levels**

At each well, establish and clearly mark the position of the selected reference point (often the north side, top of the casing). Determine the elevation of this point, record it, and state how this elevation was determined. This elevation point is important to establish the position of the piezometric surface, so it must be determined accurately.

**5. Record Background Water Levels**

To establish local trends, measure groundwater levels in all test wells and on-site surface water levels at regular intervals for several days before pumping any of the test wells. Although two days preceding the test may be enough (this meets the standards of some regulators), ideally the period of time should be at least equal to the length of the pumping test (three days to a week is optimum). Unless

extreme variations are expected, such as significantly increased stream discharge in response to off-site precipitation, only surface water bodies within the radius of influence of the pumping well need to be monitored. A well outside the radius of influence may provide valuable information about water-level trends if monitored before, during, and after the pumping test. In areas that could be influenced by tidal fluctuations, collect information regarding local tidal variations before, during, and after the test.

If levels in the zones to be monitored during the test might be affected by pumping of other nearby wells, gather information about the discharge rates and operating times of those wells. Also, monitor water levels for a sufficient period before the test to evaluate the influence of nearby wells. Water-level monitoring should be done far enough in advance to allow time to negotiate with well owners and take appropriate action. If possible, arrange to have nearby wells shut down or pumped at a constant rate to ease data interpretation.

**6. Record Barometric Pressure**

Atmospheric-pressure changes can cause water level changes in confined or semi-confined aquifers, leading to erroneous conclusions about aquifer parameters. To correct for these changes, the barometric efficiency of each appropriate aquifer must be determined. Aquifer barometric efficiency (BE), a ratio of aquifer head change to atmospheric pressure change, can be calculated using:

$$BE = \left( \frac{\Delta h}{\Delta B_p} \right) 100\,\%$$

where

BE = barometric efficiency, in percent

$\Delta h$ = change in water level resulting from change in atmospheric pressure, in feet

$\Delta B_p$, = change in atmospheric pressure, in feet of water

To measure atmospheric pressure changes, either ensure that the dataloggers being used also measure barometric pressure, or obtain data from a nearby source. Barometric pressure must be recorded throughout the background water-level-measurement period and throughout the test. Ideally, barometric pressure and water-level measurements should be made during a time of significant atmospheric pressure change so their relationship can be more easily correlated.

Logging transducers with vented cables (e.g.: Troll, miniTroll) already account for barometric pressure and no additional adjustment is required.

**7. Install a Rain Gauge**

Heavy precipitation can cause a significant water-table rise in shallow aquifers. Note that rainfall data from nearby weather stations or airports may not be representative, because precipitation patterns may vary greatly over short distances. Therefore, when testing shallow aquifers, a rain gauge should be installed at the test site and monitored during rainfall. Keep in mind that storm sewers can channel large volumes of water rapidly to shallow aquifers.

**8. Set-up: Remaining Equipment Required for Test**

a) Keep sensitive electronic equipment away from devices that generate significant magnetic fields. For example, do not place data loggers near electric power generators or electric pump motors. Likewise, radio signals may cause dataloggers or computers to malfunction.

b) Secure data logger and transducer cables at the well head to prevent movement that would affect measurements. Mark a reference point on transducer cables and check regularly to detect slippage.

c) Provide adequate lighting for night readings.

d) Identify all equipment to be used in the test that will affect data. For example, describe (by serial number or otherwise) the pump, any isolation packers, water level meters, data loggers, rain gauges, barometers, flow meters, buckets or volumetric containers, watches, and steel tapes used.

e) Consider having backups for key equipment such as data loggers, generators, water level meters, etc.

**9. Perform a Job Safety Analysis**

To ensure that everyone is aware of the hazards associated with the work, and that each person knows his/her responsibilities during the preliminary and full-scale test, run through a JSA of the test before the start of pumping.

**10. Conduct a Preliminary Pumping (Step-Drawdown) Test**

Conduct a short-term preliminary test of the pumping well to estimate the hydraulic properties of the aquifer, estimate the duration of the test, and establish a pumping rate. A step-drawdown test is the most efficient preliminary test to use. If other

constraints determine flow rate and the flow rate is sustainable, a step test is unnecessary.

The concept of step-drawdown testing in wells was first developed by Jacob (1947). He proposed that drawdown in a well has two components: formation loss (laminar, proportional to the discharge), and well loss (turbulent, proportional approximately to the square of the discharge). Jacob outlined a multiple-step drawdown test where discharge was increased at specific times, as if pumping of the well was held constant and additional wells were introduced at corresponding increases in pumping rates. Rorbaugh (1953) later noted that Jacob's assumption of second-order turbulent flow did not take into account that turbulence at low rates of discharge is not fully developed. Thus the exponent for turbulent flow should be expressed as an unknown constant. Taking this into consideration, the arithmetically-plotted results of a step-drawdown test can be used to select the discharge rate for a pumping test, determine drawdown for a given pumping rate and optimum pump depth, and even (with some minor calculations) estimate the transmissivity of the formation prior to the test. (This is also a good test for reliability of the flow meter.)

a) Select the pumping rates for the step-drawdown test based on:
    1) production capability estimates made during well development,
    2) prior pumping information,
    3) slug test data (for small wells), or
    4) a brief, preliminary rate test.

Step tests are most commonly run with three steps at 33, 67 and 100 percent or four steps at 25, 50, 75, and 100 percent of the anticipated maximum rate. Sometimes a step is added at 133 percent for a three-step test or 125 percent for a four-step test and the first step is dropped.

b) Conduct the step test, pumping at each level for 30 to 60 minutes. It is important to run the initial step long enough to establish that the effects of well storage have dissipated, with the remaining steps run for the same duration as the initial step. Although standard practice is to allow a recovery period after each step, practical experience shows that these individual recoveries are not necessary.

c) At the end of the step test, mark the setting of the discharge control valve corresponding to the flow rate for the full-scale pumping test. Secure the valve in that position with wire or tape to prevent inadvertent changes.

d) Allow sufficient time after completion for drawdown to return to static level. Although the time may vary, allow at least one day of recovery after the step-drawdown test has been completed before starting the constant-rate test.

### 11. Synchronize Watches

Just before the constant-rate test, watches and other time-measurement devices (i.e., dataloggers) should be synchronized so that the time of each reading, electronic and manual, can be referenced to the exact minute and hour that pumping started.

## III. CONDUCTING THE TEST

### 1. Record Information

a) Use appropriate data forms

b) Record all required background information on logs before beginning the test

c) Record time as military (24-hour) time.

d) Ensure that everyone taking manual water-level measurements understands the units of measurement on the device or devices they will use.

### 2. Keep Pertinent Well Construction Details at Hand

To evaluate data plotted during the test, it may be necessary to have access to well construction information, such as the following:

- Lithologic logs;
- Well depths;
- Screen lengths
- Screen type (slotted, wrapped, opening size)
- Filter pack thickness and length
- Pumped well diameter
- Pump characteristics (performance, unit dimensions)
- Pump setting depth
- Topographic maps

**3. Start the Test**

a) Check all wells to confirm that water is at static level. Record the time since last pumping.

b) Make sure all field personnel are aware of predetermined starting time.

c) Start the pump and timing devices simultaneously. Use both an audible and visible signal to indicate the start of the test, especially if the distance between the pumped well and observation wells is large.

**4. Measure Drawdown at Established Times**

The widespread use of data loggers with extended memory precludes the older standard of using logarithmic time measurements. However, remember that rapid-frequency readings are needed early in the test in order to observe early effects of pumping and formation storage, plus effects of well construction. Water level measurements should be taken at least every five seconds.

Early time data are of greater importance when conducting pumping tests to identify aquifer heterogeneities and should be collected at short time intervals (< 1 sec) and considered as part of the pumping test analysis. Large data files can be generated and may need to be manipulated with text editors prior to importing data to other software such as Excel.

For manual observation well readings, the following schedule is suggested:

| Elapsed Time | Interval Between (minutes) Measurements (minutes) |
|---|---|
| 0-5 | 1 |
| 5-15 | 2 |
| 15-60 | 5 |
| 60-120 | 10 |
| 120-300 | 30 |
| 300-1440 | 60 |
| 1440-end of test | 240 |

Drawdown readings are sometimes difficult to record at the exact time required by the above schedules. If the designated time for a drawdown reading is missed, take a reading anyway and record the actual time. However, try to follow the established schedule as closely as possible to ease data plotting. Use the following table as a guideline for time measurement accuracy.

**5. Check the Flow Measuring Device**

Unrecorded fluctuations of pumped well discharge rate can make the test data difficult to interpret. Measure and record discharge every 5 minutes during the beginning of the test. When discharge becomes stable, reduce the frequency to hourly checks.

As water levels decline, the discharge rate may decrease, thus requiring adjustment. Whenever adjusting the flow rate, record water levels in the pumped well before and after each adjustment.

**6. Monitor Fuel Levels**

When using liquid-fuel-driven engines or generators, monitor and refill fuel tanks as needed to prevent premature termination of the test.

**7. Plot Data to Evaluate Trends and Catch Aberrations**

a) Begin to tabulate and graph the elapsed time, discharge rate, and pumped well drawdown as early as possible in the test, usually after the first hour of testing.

b) Prepare a plot of the log of drawdown (log10s) versus the log of the ratio of time since pumping started to the square of the distance from the pumped well to the observation well (log10t/r2) on arithmetic graph paper and maintain during the test. Compare this data to basic type curves to detect deviations that may be due to discharge variations or other changes in field conditions that need to be documented. A portable computer and printer ease this plotting for tests with many wells.

c) Keep the plots current throughout the test. This information supports informed, intelligent decisions about test progress and may signal anomalies such as equipment malfunctions or unacceptable flow rate variations. Analysis of these plots may suggest that more data is needed to substantiate conclusions about the groundwater system.

**8. Collect Groundwater Samples and Measure Field Parameters**

Samples of discharge water may provide valuable information about the nature of aquifer water quality as it changes during the pumping test. Depending on the site conditions, samples collected regularly throughout the test may signal proximity to a contaminant source, connection with surface water bodies, or other contributors to water quality change. The number of water samples needed and the frequency and time of their collection depends on both nearness to suspected or known water quality influences and the test budget.

### 9. Verify Measuring Device Accuracy

Recheck the accuracy of hand-held electronic water-level sounders before starting the recovery portion of the test. During pumping and recovery, check transducer accuracy periodically with reliable manual devices. Every hour or few hours is sufficient for most tests.

### 10. Measure Water Levels during the Recovery Phase at Established Times

Recovery of water levels following the pumping phase should be measured immediately upon pump shut down and recorded for a period of time equal to the pumping time, or until the water levels have reached 95 percent of the initial, pre-pumping static water level. Use the same drawdown measurement schedule that was used during pumping. A check valve should be used to prevent backflow of water in the riser pipe into the well, which could result in unreliable recovery data.

Recovery phase data may be easier to analyze because no discharge fluctuations occur, and pump-induced turbulence is not a concern in the pumping well. However, note that typically the calculated transmissivity from the pumping phase will be lower than that of the recovery phase due to the added turbulence and vertical flow components during pumping.

### 11. Record Observation of Pertinent Phenomena

Record any unusual events occurring just before or during the test that may affect test data, such as:

- Weather changes
- Heavy equipment (trains, etc.) passing through area
- Operation times of other wells
- Changes in pumping rate
- Equipment problems, and
- Earthquakes

## IV. POST-TEST PROCEDURES

### 1. Document the "As-Built" Configuration of the Test

Describe the configuration of the test, the observation well locations versus the pumping well, water discharge, outside influences detected during the test, and any modifications to the original plan.

**2. Verify Timing Device Agreement and Measuring Device Accuracy**

Compare all clocks, watches, and data recorders for agreement and note any discrepancies, identifying the devices and where they were used. Compare manual measurements to datalogger measurements within wells to confirm accuracy of measuring devices.

**3. Sound the Pumped Well**

Determine if any aquifer material accumulated in the pumped well during the test. Sand or other material accumulating in the well during the test progressively blocks screen areas, reducing the effective aquifer penetration. If the effect of this condition is not taken into account, aquifer parameters calculated from test data will be wrong. Gradually decreasing aquifer penetration in a pumped well significantly complicates test data analysis. The wisest strategy, therefore, is to prevent infilling of screens by sufficient development of the pumped well.

**4. Decontaminate All Equipment Contacting Site Groundwater and Soil**

Use appropriate decontamination procedures.

**5. Monitor Background Information as Long as Possible**

If possible, continue to monitor groundwater levels, surface water levels, and barometric pressure data for several days after test completion. This information may reveal trends or relationships undetected before or during the test.

## V. SPECIAL CONSIDERATIONS

**1. Wells Containing Floating Nonaqueous Phase Liquids**

It is best to use pressure transducers to measure water levels in wells containing floating product such as gasoline. Contact with floating product, however, may make transducers and cable unsuitable for future use. Thus, include the cost of replacing transducers (and perhaps cable) when calculating pumping test budgets. Otherwise, protect each transducer and cable assembly by encasing it in plastic tubing or pipe. Be sure that each protected transducer still can respond accurately to any pressure changes.

As an alternative to pressure transducers, make manual measurements (using a interface probe) of both the fuel level and water level individually. Then correct the observed thickness of floating product by its density to arrive at an effective pumping level. Measure product density in the field using a simple density balance (such as drilling fluid balance) or consult an appropriate API table. This manual procedure will work, but takes time and introduces additional measurement and computation errors.

**2. Fill Materials**

Occasionally, pumping tests are conducted in or adjacent to fill materials. In these circumstances, it is essential that the nature of the fill and possible extremes in heterogeneity be understood and incorporated into the design of the pumping test so that the resulting data set can provide the required information.

**3. Karst and Cavernous Aquifers**

Flow through the fractures and conduits within a karst aquifer system ranges from conduit to diffuse. Conduit flow describes flow through dissolution channels with velocities commonly high and turbulent. (The presence of conduits typically requires a dual-porosity model for characterization). Diffuse flow, on the other hand, refers to a slow, mostly laminar to slightly turbulent flow through a series of small, discrete pathways that are being enlarged through dissolution. Karst aquifers do not lend themselves to conventional pumping test layout, procedures, and analysis because flow can be dominated by discrete channels. The discrete nature of high-conductivity zones can range several orders of magnitude and thus hydraulic conductivity values vary according to the scale of measurement, from local to regional. Interpretation of pumping tests must take into consideration the portion of the aquifer being tested.

Additional background investigations may need to be conducted before a pumping test is conducted, in order to predict the connectivity of the wells within the test network. This may include borehole and surface geophysics, tracer (natural and introduced) testing, spring flow and water chemistry analysis, slug testing, and lineament analysis.

**4. Fractured Aquifers**

The challenge to conducting a pumping test within a fractured-rock aquifer is the continuity of fractures can vary significantly within an area and affect its ability to provide water in a consistent manner. Many fractured aquifers also exhibit a preferred permeability direction based on predominant fracture orientations. Recharge may also vary seasonally and cause production problems in low flow periods (low water level and low recharge). During these periods excessive drawdown may occur. Typically, sources completed in bedrock composed of shale, basalt, granite or any consolidated material can have fractured flow concerns.

For these aquifer systems, although a conventional pumping test approach is generally appropriate, more observation wells will be required to determine the anisotropy and to discern both near-well and distant responses. Also, step-drawdown test data provide valuable information in fractured aquifers because flow near the well in fractured aquifers may be mostly turbulent.

## Recirculation Flow and Solute Transport Modeling

## Recirculation Flow and Solute Transport Modeling

Historical geologic and hydraulic information was utilized to develop an appropriate design well network capable of establishing a complete reactive zone within targeted intermediate and deep water-bearing zones over an initial 6-month period within the Phase I IRM treatment footprint. A groundwater flow and solute transport model was constructed for Site 114 to assess the necessary spacing, orientation, and operational sequencing of the Phase I well network. The modeling approach allowed verification of the combination of extraction and injection at Site 114 that avoids excessive hydraulic mounding within the sheet pile walls while achieving organic carbon distribution during the Phase I operational timeframe. Finally, the model serves as a tool for future optimization of the Phase I program based on additional groundwater extraction and injection information generated over the course of operation.

## Hydrogeology Implications for Groundwater Recirculation

The local hydrogeology discussed in Section 2.3 has been considered when designing and constructing the injection and extraction well network. Several key geologic conditions for the design include the following:

- Utilization of fine-grained soils associated with the meadow mat (where present) to ensure a good seal between the shallow and intermediate aquifers.
- Consideration of the hydraulic control necessary for both higher chromium (Cr) mass and volumetric flux within the intermediate water-bearing zone.
- The expected contrast in hydraulic conductivity between the intermediate and deep water-baring zones that may require discretely-screened remediation wells to address both intervals.

Existing information from Site 114 has been utilized to develop the Phase I conceptual well network, with confirmatory testing activities detailed in Section 2.5 intended to reduce uncertainties associated with the above listed observations and support final construction needs.

## Model Development and Calibration

The simulation program MODFLOW was selected for the construction of the numerical groundwater flow model at the site. MODFLOW is a publicly available groundwater flow simulation program developed by the U.S. Geological Survey (McDonald and Harbaugh 1988). MODFLOW simulates transient or steady-state, saturated groundwater flow in three dimensions. The program is designed to simplify the specification of boundary conditions by designing the data input to align with common field variables. The boundary conditions supported by MODFLOW include specified head, precipitation recharge, injection or extraction wells, evapotranspiration, horizontal flow barriers, drains, and rivers or streams. Aquifers simulated by MODFLOW can be confined, unconfined, or convertible between conditions. For the site, which consists of a heterogeneous geologic system with variable unit thicknesses and boundary conditions, MODFLOW's three-dimensional capability and boundary condition versatility are essential for the proper simulation of groundwater flow conditions.

MODFLOW uses the method of finite differences to solve the equations of groundwater flow. Using a block-centered finite-difference approach, MODFLOW replaces the continuous system represented by the equations of flow with a system of discrete blocks in space. The solution of the finite-difference equations

produces time-varying values of hydraulic head at each of the discrete points representing the real aquifer system.

The model extents are limited to the Site 114 boundary that follows the perimeter sheet pile walls as they effectively hydraulically control the majority of the site. The model is composed of four vertical layers that discretely represent the shallow fill, meadow mat, intermediate, and deep aquifers. The base of the model represents the contact between the bottom of the deep aquifer and the underlying till and/or bedrock. The thickness of each model layer was initialized based upon hydrogeologic unit contacts identified in site boring logs, geophysical surveys, and interpolated cross-sections. Hydraulic parameters, such as hydraulic conductivity and recharge, were assigned within ranges of observed values based on site slug tests, aquifer tests, and literature values. Model boundary conditions include no-flow cells to represent the perimeter sheet pile walls, hydraulic flow boundaries to represent interior sheet pile walls, head boundaries to represent the portions of the site perimeter where the existing sheet pile walls do not fully extend to the underlying till and/or bedrock, and wells to represent the proposed remedial injection and extraction wells. Figures showing the flow model construction, calibration, and results are presented in **Figure 1** shows the simulated model domain extents and boundary conditions. The model was first qualitatively calibrated to the anticipated steady state conditions of the static site groundwater elevations, accounting for a 3-foot head difference from shallow to intermediate water-bearing zones across the meadow mat. Remedy simulations were then conducted transiently to evaluate the temporal change in heads during remedy operations.

Upon completion of the construction of the groundwater flow model, the solute transport modeling was performed using the modular three-dimensional transport model referred to as Modular 3-D Transport Model (MT3D). MT3D was originally developed by Zheng (1990) at S.S. Papadopulos & Associates, Inc. for the Robert S. Kerr, Environmental Research Laboratory of the U.S. Environmental Protection Agency (USEPA). The MT3D code uses the flows computed by MODFLOW in its transport calculations. MT3D also uses the same finite-difference grid structure and boundary conditions as MODFLOW, simplifying the effort to construct the solute transport model. MT3D is regularly updated (Zheng and Wang 1999), and the most recent version is referred to in the literature as MT3D Multi-Species (MT3DMS), where MS denotes the Multi-Species structure for accommodating add-on reaction packages. MT3DMS has a comprehensive set of options and capabilities for simulating advection, dispersion/diffusion, and chemical reactions of contaminants in groundwater flow systems under a range of hydrogeologic conditions. Recent updates to MT3DMS have included the dual-domain formulation and the ability to incorporate site-specific processes.

To represent the development of the reactive zone over time, the injection of a carbon substrate was simulated. The carbon substrate is not readily sorbed in the subsurface so there was no sorption parameter simulated. Based on the pilot test data, a conservative (i.e., faster) carbon degradation half-life of 20-days was simulated. The solute transport model is simulated as dual domain with an average mobile porosity of 10% and immobile porosity of 20%. A constant organic carbon injection concentration of 100 milligrams per liter (mg/L) was assumed so it can be easily scaled to represent different proposed injection concentrations. While constant carbon delivery was assumed for model purposes, it is anticipated that Phase I operations will rely on a pulsed carbon delivery program. Phase I carbon pulsing will include total organic carbon (TOC) concentrations between 1,000 to 7,000 mg/L over a subset of the operational time, so the 100 mg/L assumption used in the model is considered a low estimate of total Phase I delivery for conservative purposes.

## Remedy Simulation

Once constructed, the groundwater flow and solute transport model was utilized to iterate a combination of remedial well infrastructure, flow rates, and operational sequencing to establish an optimal remedy design. The final design consists of 35 injection well locations and 7 extraction well locations as shown on **Figure 2**. The injection wells are located on the southern half of Site 114 within the Phase I area. The southern well network includes variable sequencing that utilizes wells operated for injection purposes and wells that are shifted from extraction to injection purposes to control hydraulic mounding during different steps of the Phase I program. Dedicated Phase I extraction wells are located on the northern half of Site 114 and are in areas of highest observed Cr concentrations to maximize mass removal. At each well location, the well location was simulated to allow access to both model layers 3 and 4 (intermediate and deep aquifers, respectively). This process allows development of a total number of well locations for the PBR and allows for modification of the actual number of discrete well intervals necessary based on observations pertaining to the local aquifer heterogeneity, saturated thickness, and Cr concentrations during confirmatory sampling and construction activities.

Iterations of the site-specific injection and extraction flow rates and the Phase I well network indicated that a combined total injection and extraction rate of 17 gallons per minute (gpm) can achieve organic carbon distribution within the southern area of Site 114 during the first 6-month period. While this flow rate was acceptable for modelling purposes, it is anticipated that wells will behave differently based on unique geologic heterogeneities in different areas of the site. It is also assumed that where achievable, injection and extraction rates will be increased to maximize the total quantity of groundwater extracted and injected, within permit specifications. The design simulation entails initiations of injection activities within the southern end of Site 114 followed by gradual northward shifts in operating wells during 8-week cycles. This modelled sequencing allows for complete carbon coverage and reactive zone development for Cr reduction throughout the Phase I injection area. **Figure 2** shows the simulated well locations and rates over the simulated 6-month period. **Figure 3** shows the active injection and extraction wells locations during each of the three stages of remedy operation.

The resulting reactive zone development at weeks 8, 16, and 26 (days 56, 112, and 182) is shown on **Figure 4**. This reactive zone is defined as the extent of the simulated relative injected carbon substrate concentration above a relative concentration of 0.1%, which reflects the combined influence of both TOC distribution and reduced groundwater geochemical extent. This allows for the simulated carbon concentration results to be directly scalable to the final proposed injection concentrations to evaluate carbon concentration distributions during active remedy conditions. The simulated reactive zone development indicates that within a 6-month period, the Phase I area will be effectively addressed with either available TOC or reduced metals – both of which work to reduce Cr.

To evaluate the drawdown and mounding, the simulated active remedy transient water levels were also reviewed in detail. The simulated steady-state water level starting conditions for model layer 1 (shallow fill) and model layer 3 (intermediate aquifer) are shown on **Figure 5**. The active remedy transient simulated water levels for model layers 1 and 3 at weeks 8, 16, and 26 are shown on **Figures 6** and **7**, respectively. These transient water levels were then directly compared to the starting steady state water levels to determine the relative hydraulic mounding and drawdown that occurs during remedy operation. **Figures 8** and **9** show the relative changes in water levels over time for model layers 1 and 3, respectively. The maximum hydraulic mounding is approximately 3.5 feet in model layer 3 and 1.5 feet in model layer 1. This indicates that simulated mounding water levels will not exceed land surface and that a neutral to downward vertical gradient is preserved between the shallow fill and the underlying intermediate and deep aquifers.

## Model Update

Through additional hydrogeologic testing, hydraulic monitoring, and water quality monitoring during confirmatory testing activities, remedial well infrastructure installation, and Phase I operation, the groundwater flow and solute transport model can be updated periodically to more accurately reflect encountered conditions. This will allow the model to be further used as predictive tools to evaluate remedy performance and assist in providing recommendations for optimization of the remedial system (i.e., injection/extraction rates and frequency, carbon dosing frequency and concentration, and need for provisional wells).

As with all mathematical models of natural systems, the groundwater flow and solute transport model is limited by factors, such as scale, accuracy of the estimated hydraulic properties and/or boundary conditions, and the underlying simplifications and assumptions incorporated into the model. These factors result in limitations to the model's appropriate uses and to the interpretations that may be made of the simulation results. The proposed remedy design and operation were based on the conceptual site model, calibrated groundwater flow model, the predictive solute transport modeling, and professional expertise related to similar remedial designs and modelling bases. This model is intended to serve as the initial basis for IRM design, considering that additional data collection prior to and during the Phase I implementation will all be used to adapt and refine treatment operations.

## Safety Data Sheets for Reagents and Substrates

**MATERIAL SAFETY DATA SHEET**
**MOLASSES/MOLASSES BLENDS/BINDERS**

## 1. CHEMICAL PRODUCT AND COMPANY IDENTIFICATION

| Chemical Name | Chemical Formula | Molecular Weight |
|---|---|---|
| N/A | Mixture of liquid Agricultural commodities | No data |

Trade Name – Molasses/Molasses Blends

Synonyms: DOT Identification No.

Liquid animal supplement: N/A

Company Identification:
Westway Trading Corporation
365 Canal Street, Suite 2900
New Orleans, Louisiana 70130
(504) 525-9741

## 2. COMPOSITION, INFORMATION ON INGREDIENTS

| Component(s), Chemical Name | CAS Registry No. | %(Approx.) | ACGIH TLV-TWA |
|---|---|---|---|
| Proprietary **See ingredient tag** | NA | No data | No data |

## 3. HAZARDS IDENTIFICATION

Emergency Overview

This material should be stored in a vented tank designed to contain a material with a specific gravity of 1.3 or greater. Material can ferment if excessive moisture contamination is allowed. Fermentation can yield carbon dioxide with possible traces of ethanol or volatile fatty acids (e.g. acetic, propionic, lactic, or butyric) and if exposed to a spark or flame may result in an explosion. These conditions should be avoided. If maintenance of tank requires entry by personnel, OSHA's Confined Space standard (29CFR1910.146) shall be complied with. If welding is to be performed, the tank should be gas freed and only certified welders shall perform welding operations.

Potential Health Effects

Eyes - Mild irritant

Skin - None

Inhalation – Insufficient oxygen may be present in vessels containing the product due to the generation of carbon monoxide during fermentation

## 4. FIRST AID MEASURES

Eyes: Flush eyes for 15 minutes.

Skin: Wash with soap and water.

Ingestion: No data

## 5. FIRE FIGHTING MEASURES

| Flashpoint (Method used) | Flammable Limits in Air |
|---|---|
| Non-flammable<br>Non-combustible | Non-flammable<br>Non-combustible |

Extinguishing Agents - NA

Unusual Fire and Explosion Hazards – Fermentation occurs when diluted with water and is accelerated by heat. During fermentation, carbon monoxide with possible traces of ethanol or volatile fatty acids (e.g., acetic, propionic, lactic, or butyric) is given off, which produces inhalation hazards and possible explosion hazards.

## 6. ACCIDENTAL RELEASE MEASURES

Steps to be Taken in Case Material is Released or Spilled

Small spills - Stop the source of the spill. Recover as much product as possible for reuse. Absorb remaining spill and dispose solids in waste container.

Large spills - Stop the source of the spill. Create diversionary structures to minimize the extent of the release. Prevent the release from entering a waterway or sewer. Recover useable product. Absorb remaining spill and dispose of at an approved facility such as a municipal landfill or land application site.

## 7. HANDLING AND STORAGE

This material should be stored in a vented tank designed to contain a material with a specific gravity of 1.3 or greater. Material can ferment if excessive moisture contamination is allowed.

## 8. EXPOSURE CONTROLS, PERSONAL PROTECTION

Respiratory Protection - None

Ventilation – Provide adequate ventilation to prevent accumulation of vapors.

Skin Protection - Rubber gloves

Eye Protection - Safety glasses

Hygiene - Wash any exposed area promptly with soap and water. Launder contaminated clothing.

Other Control Measures - None

## 9. PHYSICAL AND CHEMICAL PROPERTIES

| | |
|---|---|
| Appearance<br>Dark brown syrupy liquid | Odor<br>Sweet |
| Physical State<br>Liquid | Specific Gravity<br>1.45 |
| Boiling Point<br>Very high | Freezing/Melting Point<br>Varies |
| Vapor Pressure<br>Low | % Volatile, by Volume<br>No data |
| Evaporation Rate<br>No data | Vapor Density in Air<br>Water vapor only |
| Solubility in Water<br>Soluble | pH<br>2.25 to 6.0 |

## 10. STABILITY AND REACTIVITY

Chemical Stability - Stable

Conditions to Avoid – Excess moisture or heat. Unventilated containers.

Incompatibility with Other Materials - Reacts with concentrated nitric acid or concentrated Sulphuric acid. Ferments when diluted with water.

Hazard Decomposition Products – Carbon monoxide, alcohol or fatty acid vapors

Hazardous Polymerization - NA

## 11. ECOLOGICAL INFORMATION

Prevent releases to land or water. Results in high Biological Oxygen Demand (BOD) and potential oxygen depletion of aquatic systems.

## 12. DISPOSAL CONSIDERATIONS

Dispose of waste material at an approved municipal landfill or land application site.

## 13. TRANSPORT INFORMATION

Hazardous Materials Description/ Proper Shipping Name - NA

DOT Hazard Class - NA

DOT Identification Number - NA

X  This product is not a DOT hazardous material.

## 14. REGULATORY INFORMATION

Discharges to a water of the U.S. are regulated by the Environmental Protection Agency.

## 15. OTHER INFORMATION

None.

Date of Preparation: 3/15/96 **REVISED: 10/12/01**

EOS Remediation, LLC

# EOS PRO

## SAFETY DATA SHEET

| Section 1: Identification | |
|---|---|
| Product Name: | **EOS Pro** |
| Chemical Description: | Mixture; vegetable oil emulsion |
| Manufacturer: | EOS Remediation<br>1101 Nowell Road<br>Raleigh, NC 27607<br>(P): 919-873-2204<br>www.eosremediation.com |
| Recommended Use: | Groundwater bioremediation (environmental applications) |
| Restricted Use: | Not for human consumption. |
| 24-Hour Emergency Contact: | ChemTel: United States<br>(P): 800-255-3924<br>ChemTel: International<br>(P): 813-248-0585 |

| Section 2: Hazard(s) Identification | |
|---|---|
| Hazard Classification: | Irritant (skin and eye) |
| Signal Word: | Warning |
| Hazard Statement(s): | Potential eye and skin irritant. |
| Pictograms: |  |
| Precautionary Statement(s): | Not for human consumption. Do not store near excessive heat or oxidizers. Avoid contact with eyes and skin. Wear protective gloves and eye protection. |

| Section 3: Composition/Information on Ingredients | | |
|---|---|---|
| **Common Name(s)** | **CAS NO.** | **% by Weight** |
| Soybean Oil | 8001-22-7 | 59.8 |
| Food Grade Emulsifiers<br>Trade Secret[1,2] | Proprietary | 10 |
| Soluble Substrates<br>Trade Secret[1,2] | Proprietary | 4 |
| Food Additives/Preservatives<br>Trade Secret[1] | Proprietary | 0.3 |
| Nutrients/Extracts<br>Trade Secret[1,2] | Proprietary | 1 |
| Water | 7732-18-5 | Balance |

1 – The precise composition of this product is proprietary information. A more complete disclosure will be provided to a physician in the event of a medical emergency.

2 – The soluble substrates and emulsifiers are generally recognized as safe for food contact.

| Section 4: First-Aid Measures | |
|---|---|
| **Routes of Exposure** | **Emergency First-Aid Procedures** |
| Inhalation | Remove to fresh air. |
| Eye Contact | Flush with water for 15 minutes; if irritation persists see a physician. |
| Skin Contact | Wash with mild soap and water. |
| Ingestion | Product is non-toxic. If nausea occurs, induce vomiting and seek medical attention. |

| Section 5: Fire-Fighting Measures | |
|---|---|
| Extinguishing Media: | $CO_2$, foam, dry chemical<br>Note: Water, fog and foam may cause frothing and spattering. |
| Special Fire Fighting Procedures: | Wear self-contained breathing apparatus and chemical resistant clothing. Use water spray to cool fire exposed containers. |
| Fire Hazard(s): | Burning will cause oxides of carbon. |

| Section 6: Accidental Release Measures | |
|---|---|
| Personal Precautions: | Avoid contact with eyes and skin. Do not consume. |
| Emergency Procedures: | N/A |
| Methods & Materials used for Containment: | Compatible granular absorbent |
| Cleanup Procedures: | Spread compatible granular absorbent over spill area and sweep using broom and pan; dispose in appropriate receptacle. Clean area with water. |

| Section 7: Handling and Storage | |
|---|---|
| Safe Handling & Storage: | Do not store near excessive heat or oxidizers. |
| Other Precautions: | Consumption of food and beverages should be prevented in work area where product is being used. After handling product, always wash hands and face thoroughly with soap and water before eating, drinking, or smoking. |

| Section 8: Exposure Controls/Personal Protection | | |
|---|---|---|
| **Exposure Limits** | | |
| OSHA PEL: | NE | |
| ACGIH TLV: | NE | |
| NIOSH REL: | NE | |
| **Personal Protective Measures** | | |
| Respiratory Protection: | Not normally required. P95 respirator if aerosols might be generated. | |
| Hand Protection: | Protective gloves are recommended | |
| Eye Protection: | Recommended | |
| Engineering Measures: | Local exhaust ventilation if aerosols are generated | |
| Hygiene Measures: | Wash promptly with soap & water if skin becomes irritated from contact. | |
| Other Protection: | Wear appropriate clothing to prevent skin contact. | |

| Section 9: Physical and Chemical Properties | | | |
|---|---|---|---|
| Appearance: | White Liquid | Explosive Limits: | NE |
| Odor: | Vegetable Oil | Vapor Pressure: | NE |
| Odor Threshold: | NE | Vapor Density: | Heavier than air |
| pH: | Neutral | Relative Density: | 0.96-0.98 |
| Melting Point/Freezing Point: | Liquid at room temperature | Solubility: | Dispersible |
| Boiling Point: | 212°F (100°C) | Partition coefficient: | NE |
| Flash Point: | >300°F (149°C) | Auto-ignition Temperature: | NE |
| Evaporation Rate: | NE | Decomposition Temperature: | N/A |
| Flammability (solid, gas): | NE | Viscosity: | 500-1500 cP |

NE – Not Established

| Section 10: Stability and Reactivity | |
|---|---|
| Stability: | Stable |
| Incompatibility: | Strong acids and oxidizers |
| Hazardous Decomposition Products: | Thermal decomposition may produce oxides of carbon |
| Hazardous Reactions/Polymerization: | Will not occur |
| Conditions to Avoid: | None known |

| Section 11: Toxicological Information | | |
|---|---|---|
| Likely Routes of Exposure: | | Ingestion, dermal and eye contact |
| Signs and Symptoms of Exposure: | | None known |
| Health Hazards | | |
| | Acute: | Potential eye and skin irritant |
| | Chronic: | None known |
| Carcinogenicity | | |
| | NTP: | No |
| | IARC: | No |
| | OSHA: | No |

| Section 12: Ecological Information (non-mandatory) |
|---|
| There is no data on the ecotoxicity of this product. |

| Section 13: Disposal Considerations (non-mandatory) | |
|---|---|
| Waste Disposal Methods: | Dispose of according to Federal and local regulations for non-hazardous waste. Recycle, if practical. |

| Section 14: Transport Information (non-mandatory) |
|---|
| The product is not covered by international regulation on the transport of dangerous goods. |
| No transport warning required. |

| Section 15: Regulatory Information (non-mandatory) |
|---|
| N/A |

| Section 16: Other Information | |
|---|---|
| Date of Preparation: | 29 May 2014 |
| Last Modified Date: | 5 September 2014 |
| The information contained herein is based on available data and is believed to be correct. However, EOS Remediation, LLC makes no warranty, expressed or implied, regarding the accuracy of this data or the results to be obtained thereof. This information and product are furnished on the condition that the person receiving them shall make his/her own determination as to the suitability of the product for his/her particular purpose. | |

# Safety Data Sheet
# Calmet®

**SDS Number:** 1535 **Revision:** March 19, 2015

## Section 1: IDENTIFICATION

**1.1 Product Name:** **Calmet®**

**1.2 Other Identification:**

Chemical Family: Inorganic salt solution
Formula: $CaS_x$

**1.3 Recommended Use of Chemical:** Metal precipitant

**1.4 Manufacturer:** Tessenderlo Kerley, Inc.
2255 N. 44th Street, Suite 300
Phoenix, Arizona 85008-3279

Information: (602) 889-8300

**1.5 Emergency Contact:**

| | |
|---|---|
| Tessenderlo Kerley, Inc. | (800) 877-1737 |
| CHEMTREC | (800) 424-9300 (Domestic) |
| | (703) 527-3887 (International) |

## Section 2: HAZARD(S) IDENTIFICATION

**2.1 Hazard Classification:**

| | | |
|---|---|---|
| Health | Acute Oral Toxicity | Category 4 |
| | Acute Dermal Toxicity | Category 4 |
| | Acute Inhalation Toxicity | Category 4 |
| | Skin Corrosion/Irritation | Category 2 |
| | Eye Damage/Irritation | Category 2B |
| Physical | None | |

**2.2 Signal Word:** Warning

**2.2.1 Hazard Statement(s):**

Harmful if swallowed.
Harmful in contact with skin.
Harmful if inhaled.
Causes skin irritation.
Causes eye irritation.

**2.2.2 Symbol(s):**

**2.2.3 Precautionary Statement(s):**

**If swallowed**: Rinse mouth. Call a poison center/doctor/regional medical center if you feel unwell.
**If on skin**: Wash with plenty of water. Take off contaminated clothing and wash before reuse. Continue rinsing. Call a poison center/doctor/regional medical center if you feel unwell.
**If inhaled**: Remove person to fresh air and make comfortable for breathing. Call poison center/doctor/regional medical center if you feel unwell.
**If in eyes**: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. If eye irritation occurs: Get medical advice/attention.
Wash hands and face thoroughly with water after handling. Do not eat, drink or smoke when using this product.
Wear neoprene rubber chemical suit, gloves, goggles/full-face shield when handling product.
Avoid breathing product fume/gas/mist/vapors/spray.
Use only outdoors or in well-ventilated area.
Dispose of contents/container to chemical waste facility in accordance with local/regional/federal regulations.
Do not allow release to waterways (potential aquatic toxicity).

**2.3 Unclassified Hazard(s):** Aquatic toxicity.

**2.4 Unknown Toxicity Ingredient:** None

## Section 3: COMPOSITION/INFORMATION ON INGREDIENTS

**3.1 Chemical Ingredients** (See Section 8 for exposure guidelines):

| Chemical | Synonym Common Name | CAS No. | EINECS No. | % by Wt. |
|---|---|---|---|---|
| Calcium polysulfide, $CaS_x$ | Lime sulfur, calcium sulfide | 1344-81-6 | 215-709-2 | 24 - 29 |
| Water | Water | 7732-18-5 | 231-791-2 | Remaining % |

## Section 4: FIRST AID MEASURES

**4.1 Symptoms/Effects:**

Acute: Eye contact may cause eye irritation. Repeated or prolonged skin contact may cause skin irritation. Ingestion may irritate the gastrointestinal tract.

Chronic: No known chronic effects.

**4.2 Eyes:** Immediately flush with large quantities of water for 15 minutes. Hold eyelids apart during irrigation to insure thorough flushing of the entire area of the eye and lids. Obtain medical attention if irritation occurs.

**4.3 Skin:** Immediately flush with large quantities of water. Remove contaminated clothing under a safety shower. Continue rinsing. Obtain medical attention if irritation occurs.

**4.4 Ingestion:** If victim is conscious, give 2 to 4 glasses of water and induce vomiting by touching finger to back of throat. Obtain immediate medical attention.

**4.5 Inhalation:** Remove victim from contaminated atmosphere. If breathing is labored, administer oxygen. If breathing has ceased, clear airway and start CPR. Obtain immediate medical attention.

## Section 5: FIRE FIGHTING MEASURES

**5.1 Flammable Properties:** (See Section 9, for additional flammable properties)

**NFPA: Health – 2 Flammability – 0 Reactivity - 0**

Heating this product will evolve hydrogen sulfide vapors.

**5.2 Extinguishing Media:**

**5.2.1 Suitable Extinguishing Media:** Not flammable, use media suitable for combustibles involved in fire.

**5.2.2 Unsuitable Extinguishing Media:** Not applicable.

**5.3 Protection of Firefighters:**

**5.3.1 Specific Hazards Arising from the Chemical:**

**Physical Hazards:** Heating (flames) of closed or sealed containers may cause violent rupture of container due to thermal expansion of compressed gases.

**Chemical Hazards:** Heating causes release of hydrogen sulfide vapors. Vapors are irritating to eyes, skin and respiratory tract.

**5.3.2 Protective Equipment and Precautions for Firefighters:**

Firefighters should wear self-contained breathing apparatus (SCBA) and full fire-fighting turnout gear. Keep containers/storage vessels in fire area cooled with water spray.

## Section 6: ACCIDENTAL RELEASE MEASURES

**6.1 Personal Precautions:** Use personal protective equipment specified in Section 8. Isolate the release area and deny entry to unnecessary, unprotected and untrained personnel.

**6.2 Environmental Precautions:**

Keep out of “waters of the United States” because of potential aquatic toxicity (See Section 12).

**6.3 Methods of Containment:**

**Small Release:** Confine and absorb small releases on sand, earth or other inert absorbents.

**Large Release:** Shut off release if safe to do so. Dike spill area with earth, sand or other inert absorbents to prevent runoff into surface waterways (potential aquatic toxicity).

**6.4 Method for Cleanup:**

**Small Release:** For small areas shovel up absorbed material and place in drums for disposal as a chemical waste.

**Large Release:** Recover as much of the spilled product using portable pump and hoses. Treat remaining material as a small release (above).

## Section 7: HANDLING and STORAGE

**7.1 Handling:** Avoid contact with eyes. Use only in a well-ventilated area. Wash thoroughly after handling. Avoid prolonged or repeated breathing of vapors. Avoid prolonged or repeated contact with the skin.

**7.2 Storage:** Store in well-ventilated areas. Do not store combustibles in the area of storage vessels. Keep away from any sources of heat or flame. Store totes and smaller containers out of direct sunlight at moderate temperatures.

## Section 8: EXPOSURE CONTROLS/PERSONAL PROTECTION

**8.1 Exposure Guidelines:**

| Chemical | OSHA PELs | | ACGIH TLVs | |
|---|---|---|---|---|
| | TWA | STEL | TLV | STEL |
| Hydrogen sulfide | 20 ppm (Ceiling) | ---- | 1 ppm | 5 ppm |

**8.2 Engineering Controls:** Use adequate exhaust ventilation to prevent inhalation of product vapors. Keep eye wash/safety shower in areas where product is commonly handled.

**8.3 Personal Protective Equipment (PPE):**

**8.3.1 Eye/Face Protection:** Chemical goggles and a full face shield.

**8.3.2 Skin Protection:** Neoprene rubber gloves and suit should be worn to prevent repeated or prolonged contact with the liquid. Wash contaminated clothing prior to reuse.

**8.3.3 Respiratory Protection:**

Have self-contained breathing apparatus (SCBA), positive pressure, MSHA/NIOSH (approved or equivalent) available in case of spillage or equipment failure.

**8.3.4 Hygiene Considerations:**

Common good industrial hygiene practices should be followed, such as washing thoroughly after handling and before eating or drinking.

## Section 9: PHYSICAL and CHEMICAL PROPERTIES

| | |
|---|---|
| **9.1 Appearance:** | Ruby-red liquid |
| **9.2 Odor:** | Odor of rotten eggs |
| **9.3 Odor Threshold:** | 4.7 ppb (hydrogen sulfide) |
| **9.4 pH:** | 11.5 – 11.7, Typical |
| **9.5 Melting Point/Freezing Point:** | 18 to 25°F (-7.7 to -3.9°C), Typical |
| **9.6 Boiling Point:** | Not determined |
| **9.7 Flash Point:** | Not applicable |
| **9.8 Evaporation Rate:** | Not determined |
| **9.9 Flammability:** | Not applicable |
| **9.10 Upper/Lower Flammability Limits:** | Not applicable |
| **9.11 Vapor Pressure:** | Not determined |
| **9.12 Vapor Density:** | Not determined |
| **9.13 Relative Density:** | 1.27 (10.6 lbs/gal), Typical |
| **9.14 Solubility:** | Miscible |
| **9.15 Partition Coefficient:** | Data not available. |
| **9.16 Auto-ignition Temperature:** | Not applicable. |
| **9.17 Decomposition Temperature:** | Not determined. |
| **9.18 Viscosity:** | 2.95 cSt @ 20°C, 2.5 cSt @ 30°C. |

## Section 10: STABILITY and REACTIVITY

| | |
|---|---|
| **10.1 Reactivity:** | Strong oxidizers and acids. |
| **10.2 Chemical Stability:** | This is a stable product under conditions of ambient temperature and pressure. |
| **10.3 Possibility of Hazardous Reactions:** | Interaction with strong oxidizers, acids or acidic materials. |
| **10.4 Conditions to Avoid:** | Interaction with strong oxidizers or acidic materials (evolution of hydrogen sulfide vapors). |
| **10.5 Incompatible:** | Strong oxidizers can cause explosive mixtures if heated to dryness. Acids, acidic materials and dilution with water will cause the release of highly toxic hydrogen sulfide vapors. |
| **10.6 Hazardous Decomposition Products:** | Hydrogen sulfide and oxides of sulfur. |

## Section 11: TOXICOLOGICAL INFORMATION

| | |
|---|---|
| **11.1 Oral:** | Oral Rat $LD_{50}$: 820 mg/kg. |
| **11.2 Dermal:** | Dermal Rabbit $LD_{50}$: > 2,000 mg/kg. |
| **11.3 Inhalation:** | INH-Rat $LC_{50}$: 3.6 mg/L (4 hr. exposure). |
| **11.4 Eye:** | Data not available. |
| **11.5 Chronic/Carcinogenicity:** | Not listed in NTP, IARC or by OSHA. |
| **11.6 Teratology:** | Data not available. |
| **11.7 Reproduction:** | Data not available. |

**11.8 Mutagenicity:** Data not available.

## Section 12: ECOLOGICAL INFORMATION

**12.1 Ecotoxicity:** Green Algae, $EC_{50}$: 16.4 mg/l.

Water Flea, $EC_{50}$: 13.7 mg/l.

Bluegill, $LC_{50}$: 52.9 mg/l.

Fathead Minnow, $LC_{50}$: 42.9 mg/l.

Rainbow Trout, $LC_{50}$: 8.8mg/l.

**12.2 Persistence & Degradability:** No data is available.

**12.3 Bioaccumulative Potential:** This product is not bioaccumulative.

**12.4 Mobility in Soil:** No data available.

**12.5 Other Adverse Effects:** None

## Section 13: DISPOSAL CONSIDERATIONS

Consult federal, state and local regulations for disposal regulations.

## Section 14: TRANSPORT INFORMATION

**14.1 Basic Shipping Description:**

**14.1.1 Proper Shipping Name:** Calcium polysulfide solution *(Not regulated by DOT)*
**14.1.2 Hazard Classes:** Not applicable
**14.1.3 Identification Number:** Not applicable
**14.1.4 Packing Group:** Not applicable
**14.1.5 Hazardous Substance:** No
**14.1.6 Marine Pollutant:** No

**14.2 Additional Information:**

**14.2.1 Other DOT Requirements:**

**14.2.1.1 Reportable Quantity:** No
**14.2.1.2 Placard(s):** Not applicable
**14.2.1.3 Label(s):** Not applicable
**14.2.2 USCG Classification:** Not determined.

**14.2.3 International Transportation:**

**14.2.3.1 IMO:** Environmentally hazardous substance, liquid, n.o.s. (calcium polysulfide)

| | |
|---|---|
| **14.2.3.2 IATA:** | Non-hazardous under IATA regulations. |
| **14.2.3.3 TDG (Canada):** | Not regulated – See US DOT Section 14.1.1. |
| **14.2.3.4 ADR (Europe):** | Environmentally hazardous substance, liquid, n.o.s. (calcium polysulfide) |
| **14.2.3.5 ADG (Australia):** | Environmentally hazardous substance, liquid, n.o.s. (calcium polysulfide) |
| **14.2.4 Emergency Response Guide:** | Not applicable |
| **14.2.5 ERAP - Canada:** | Not applicable |
| **14.2.6 Special Precautions:** | Not applicable |
| **14.2.7 RR STCC** | 2899991 |

## Section 15: REGULATORY INFORMATION

### 15.1 U.S. Federal Regulations:

**15.1.1 OSHA:** This product meets the criteria of the Federal OSHA Hazard Communication Standard (29 CFR 1910.1200).

**15.1.2 TSCA:** Product is contained in USEPA Toxic Substance Control Act Inventory.

**15.1.3 CERCLA:** Reportable Quantity – Not applicable

**15.1.4 SARA Title III:**

**15.1.4.1 Extremely Hazardous Substance (EHS):** No

**15.1.4.2 Section 312 (Tier II) Ratings:**

| | |
|---|---|
| Immediate (acute) | Yes |
| Fire | No |
| Sudden Release | No |
| Reactivity | No |
| Delayed (chronic) | No |

**15.1.4.3 Section 313 (FORM R):** Not applicable

**15.1.5 RCRA**: Not applicable

**15.1.6 CAA** (Hazardous Air Pollutant/HAP): Not applicable

### 15.2 International Regulations:

**15.2.1 Canada:**

**15.2.1.1 WHMIS:** Not determined

**15.2.1.2 DSL/NDSL:** Listed in NDSL, Record No. 28636

### 15.3 State Regulations:

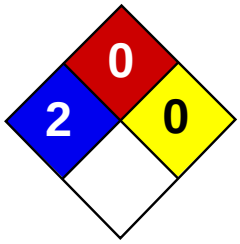
**CA Proposition 65:** No

## Section 16: OTHER INFORMATION

**REVISIONS:** This SDS was reformatted to comply with the new Hazard Communication Standard dated March 26, 2012, by the Regulatory Affairs Department of Tessenderlo Kerley, Inc. 7/1/2014.

Revised multiple sections for formatting and wording. 3/19/15.

*The information above is believed to be accurate and represents the best information currently available to Tessenderlo Kerley, Inc.(TKI). No warranty of merchantability, fitness for any particular purpose, or any other warranty is expressed or is to be implied regarding the accuracy or completeness of this information, the results to be obtained from the use of this information or the product, the safety of this product, or the hazards related to its use. Users should make their own investigations to determine the suitability of the information for their particular purpose and on the condition that they assume the risk of their use thereof. TKI reserves the right to revise this Safety Data Sheet periodically as new information becomes available.*



# Material Safety Data Sheet
## Ferrous sulfate MSDS

## Section 1: Chemical Product and Company Identification

**Product Name:** Ferrous sulfate

**Catalog Codes:** SLF1516

**CAS#:** 13463-43-9

**RTECS:** Not available.

**TSCA:** TSCA 8(b) inventory: No products were found.

**CI#:** Not available.

**Synonym:** Ferrous Sulfate Hydrate; Ferrous Sulfate Dried Powder

**Chemical Name:** Ferrous Sulfate

**Chemical Formula:** FeSO4.xH2O

**Contact Information:**

**Sciencelab.com, Inc.**
14025 Smith Rd.
Houston, Texas 77396

US Sales: **1-800-901-7247**
International Sales: **1-281-441-4400**

Order Online: ScienceLab.com

**CHEMTREC (24HR Emergency Telephone), call:** 1-800-424-9300

**International CHEMTREC, call:** 1-703-527-3887

**For non-emergency assistance, call:** 1-281-441-4400

## Section 2: Composition and Information on Ingredients

**Composition:**

| Name | CAS # | % by Weight |
|---|---|---|
| Ferrous sulfate | 13463-43-9 | 100 |

**Toxicological Data on Ingredients:** Ferrous sulfate LD50: Not available. LC50: Not available.

## Section 3: Hazards Identification

**Potential Acute Health Effects:** Hazardous in case of skin contact (irritant), of eye contact (irritant), of ingestion, of inhalation.

**Potential Chronic Health Effects:**
CARCINOGENIC EFFECTS: Not available. MUTAGENIC EFFECTS: Not available. TERATOGENIC EFFECTS: Not available. DEVELOPMENTAL TOXICITY: Not available. The substance may be toxic to kidneys, liver, cardiovascular system, central nervous system (CNS). Repeated or prolonged exposure to the substance can produce target organs damage.

## Section 4: First Aid Measures

**Eye Contact:**
Check for and remove any contact lenses. In case of contact, immediately flush eyes with plenty of water for at least 15 minutes. Cold water may be used. Get medical attention.

**Skin Contact:**
In case of contact, immediately flush skin with plenty of water. Cover the irritated skin with an emollient. Remove contaminated clothing and shoes. Cold water may be used.Wash clothing before reuse. Thoroughly clean shoes before reuse. Get medical attention.

**Serious Skin Contact:**
Wash with a disinfectant soap and cover the contaminated skin with an anti-bacterial cream. Seek medical attention.

**Inhalation:**
If inhaled, remove to fresh air. If not breathing, give artificial respiration. If breathing is difficult, give oxygen. Get medical attention.

**Serious Inhalation:** Not available.

**Ingestion:**
Do NOT induce vomiting unless directed to do so by medical personnel. Never give anything by mouth to an unconscious person. If large quantities of this material are swallowed, call a physician immediately. Loosen tight clothing such as a collar, tie, belt or waistband.

**Serious Ingestion:** Not available.

## Section 5: Fire and Explosion Data

**Flammability of the Product:** Non-flammable.

**Auto-Ignition Temperature:** Not applicable.

**Flash Points:** Not applicable.

**Flammable Limits:** Not applicable.

**Products of Combustion:** Not available.

**Fire Hazards in Presence of Various Substances:** Not applicable.

**Explosion Hazards in Presence of Various Substances:**
Risks of explosion of the product in presence of mechanical impact: Not available. Risks of explosion of the product in presence of static discharge: Not available.

**Fire Fighting Media and Instructions:** Not applicable.

**Special Remarks on Fire Hazards:** Not available.

**Special Remarks on Explosion Hazards:** Not available.

## Section 6: Accidental Release Measures

**Small Spill:**
Use appropriate tools to put the spilled solid in a convenient waste disposal container. Finish cleaning by spreading water on the contaminated surface and dispose of according to local and regional authority requirements.

**Large Spill:**
Use a shovel to put the material into a convenient waste disposal container. Finish cleaning by spreading water on the contaminated surface and allow to evacuate through the sanitary system. Be careful that the product is not present at a concentration level above TLV. Check TLV on the MSDS and with local authorities.

## Section 7: Handling and Storage

**Precautions:**
Do not breathe dust. Wear suitable protective clothing. In case of insufficient ventilation, wear suitable respiratory equipment. If you feel unwell, seek medical attention and show the label when possible. Avoid contact with skin and eyes.

**Storage:**
Hygroscopic. Keep container tightly closed. Keep container in a cool, well-ventilated area. Do not store above 24°C (75.2°F).

## Section 8: Exposure Controls/Personal Protection

**Engineering Controls:**
Use process enclosures, local exhaust ventilation, or other engineering controls to keep airborne levels below recommended exposure limits. If user operations generate dust, fume or mist, use ventilation to keep exposure to airborne contaminants below the exposure limit.

**Personal Protection:**
Splash goggles. Lab coat. Dust respirator. Be sure to use an approved/certified respirator or equivalent. Gloves.

**Personal Protection in Case of a Large Spill:**
Splash goggles. Full suit. Dust respirator. Boots. Gloves. A self contained breathing apparatus should be used to avoid inhalation of the product. Suggested protective clothing might not be sufficient; consult a specialist BEFORE handling this product.

**Exposure Limits:** Not available.

## Section 9: Physical and Chemical Properties

**Physical state and appearance:** Solid.

**Odor:** Not available.

**Taste:** Not available.

**Molecular Weight:** 151.9 g/mole + H20

**Color:** Grayish -white to yellowish. (Light.)

**pH (1% soln/water):** Not available.

**Boiling Point:** Not available.

**Melting Point:** Not available.

**Critical Temperature:** Not available.

**Specific Gravity:** Not available.

**Vapor Pressure:** Not applicable.

**Vapor Density:** Not available.

**Volatility:** Not available.

**Odor Threshold:** Not available.

**Water/Oil Dist. Coeff.:** Not available.

**Ionicity (in Water):** Not available.

**Dispersion Properties:** See solubility in water.

**Solubility:** Soluble in cold water.

## Section 10: Stability and Reactivity Data

**Stability:** The product is stable.

**Instability Temperature:** Not available.

**Conditions of Instability:** Incompatibles

**Incompatibility with various substances:** Not available.

**Corrosivity:** Not available.

**Special Remarks on Reactivity:**
Hygroscopic. Loses water at about 300 C. No other information found.

**Special Remarks on Corrosivity:** Not available.

**Polymerization:** Will not occur.

## Section 11: Toxicological Information

**Routes of Entry:** Inhalation. Ingestion.

**Toxicity to Animals:**
LD50: Not available. LC50: Not available.

**Chronic Effects on Humans:** May cause damage to the following organs: kidneys, liver, cardiovascular system, central nervous system (CNS).

**Other Toxic Effects on Humans:** Hazardous in case of skin contact (irritant), of ingestion, of inhalation.

**Special Remarks on Toxicity to Animals:** Not available.

**Special Remarks on Chronic Effects on Humans:** May affect genetic material (mutagenic)

**Special Remarks on other Toxic Effects on Humans:**
Acute Potential Health Effects: Skin: May cause skin irritation. Eyes: May cause eye irritation. Inhalation: May cause respiratory tract irritation. Ingestion: Harmful if swallowed. May cause gastrointestinal tract distrubances and irritation with nausea, vomiting, colic, constipation, diarrhea, black stool. May also affect behavior/Central Nervous System (somnolence -general depressed activity), respiration, cardiovascular system, liver, kidneys (pink urine discoloration). Chronic Potential Health Effects: Repeated exposure via ingestion may increase iron levels in the liver, and spleen. Damage may occur to spleen and liver.

## Section 12: Ecological Information

**Ecotoxicity:** Not available.

**BOD5 and COD:** Not available.

**Products of Biodegradation:**
Possibly hazardous short term degradation products are not likely. However, long term degradation products may arise.

**Toxicity of the Products of Biodegradation:** The product itself and its products of degradation are not toxic.

**Special Remarks on the Products of Biodegradation:** Not available.

## Section 13: Disposal Considerations

**Waste Disposal:**
Waste must be disposed of in accordance with federal, state and local environmental control regulations.

## Section 14: Transport Information

**DOT Classification:** Not a DOT controlled material (United States).

**Identification:** Not applicable.

**Special Provisions for Transport:** Not applicable.

## Section 15: Other Regulatory Information

**Federal and State Regulations:** No products were found.

**Other Regulations:** OSHA: Hazardous by definition of Hazard Communication Standard (29 CFR 1910.1200).

**Other Classifications:**

**WHMIS (Canada):** Not controlled under WHMIS (Canada).

**DSCL (EEC):**
R36/38- Irritating to eyes and skin. S2- Keep out of the reach of children. S46- If swallowed, seek medical advice immediately and show this container or label.

**HMIS (U.S.A.):**

**Health Hazard:** 2

**Fire Hazard:** 0

**Reactivity:** 0

**Personal Protection:** E

**National Fire Protection Association (U.S.A.):**

**Health:** 2

**Flammability:** 0

**Reactivity:** 0

**Specific hazard:**

**Protective Equipment:**
Gloves. Lab coat. Dust respirator. Be sure to use an approved/certified respirator or equivalent. Splash goggles.

## Section 16: Other Information

**References:** Not available.

**Other Special Considerations:** Not available.

Re: Discharge Approval and Monitoring Requirements Associated with
Permit-By-Rule Discharge Authorization for PPG Industries (COPR)
Garfield Avenue Group and Former Halladay Street Gas Works
900 Garfield Avenue; Block: 21501, Lots: 16,17,18, 19, and 20
NJ Program Interest Numbers: G000008791
Jersey City, Hudson County

Dear Mr. Terril:

This New Jersey Pollutant Discharge Elimination System/Discharge to Ground Water (NJPDES/DGW) authorization is hereby issued under the authority of the New Jersey Water Pollution Control Act, N.J.S.A. 58:10A-1 et seq. and the implementing regulations, N.J.A.C. 7:14A-1 et seq. N.J.A.C. 7:14A-7.5 authorizes the discharge described below which will allow the recovery and treatment of contaminated ground water, as well as implementation of in-situ remediation of contaminated ground water at the above referenced site.

Pursuant to N.J.A.C. 7:14A-22.4(b)5, a Treatment Works Approval is not required for discharges to ground water authorized pursuant to N.J.A.C. 7:14A-7.5 or 8.5 and a licensed operator is not required pursuant to N.J.A.C. 7:10A-1.10(c)1. The discharge shall be conducted as proposed in the June 2017 *Groundwater Interim Remedial Measure (IRM): Phase I Design and Permit-By-Rule (PBR) Authorization Request*, received on 30 June 2017 and clarified and revised as described in meeting minutes circulated on 11 September 2017, and the email correspondence of 14 September 2017. This document and supporting clarification information was submitted by James McLaughlin, Matthew Schnobrich, and John Horst of Arcadis U.S. Inc., on behalf of PPG Industries.

A public notice describing this discharge was published in The Jersey Journal on 29 July 2017 which initiated a 30-day public comment period. In addition, a copy of the public notice has been sent to the Municipal Clerk and designated local health official for Jersey City and Hudson County. The Department did not receive any comments on the DGW proposal.

Pursuant to N.J.A.C. 7:14A-2.7 the maximum approved discharge duration is five (5) years from the date of this letter, regardless of the date when the discharge first occurs. The Department shall be notified of the date when the discharge begins as instructed in section IV of this letter. Only the discharge described in Section I below is authorized. The discharge shall be conducted in conformance with the above mentioned DGW proposal and shall comply with the requirements of Sections II, III, and IV, farther below.

## I. DISCHARGE DESCRIPTION

The authorized discharge includes organic carbon substrate (e.g., molasses and/or emulsified vegetable oil [EVO]) which will be mixed with treated groundwater recovered from the site. Groundwater will be recovered from the northern portion of Site 114, from an area containing the highest total chromium (Cr) and hexavalent chromium (Cr[VI]) concentrations, and will also be recovered from areas in southern Site 114 to enhance the organic carbon recirculation program. Groundwater will be treated using an on-site water treatment plant to provide direct treatment of Cr and Cr(VI). Treatment of the recovered water will also make it suitable for re-injection with organic carbon substrate.

The treated water will be amended with substrates to provide a degradable source of organic carbon within the subsurface to support an in situ anaerobic bioprecipitation (ISAB) approach. Both dilute organic carbon and treated water will be reinjected in the southern portion of Site 114, where concentrations of Cr are lower and more amenable to rapid bioremediation. The organic carbon will stimulate several primary mechanisms that: (1) promote the in-situ reduction of Cr(VI) to trivalent Cr (Cr[III]); and (2) support the development of an environment that enables the precipitation and fixation of Cr within the aquifer matrix.

The combination of groundwater extraction from the northern area of Site 114 and portions of southern Site 114 with reinjection in southern Site 114 will help maintain the hydraulic balance inside the sheet pile enclosure around Site 114 and may also support flushing of Cr mass toward the extraction wells to speed up the reduction of Cr concentrations in the groundwater.

The IRM Phase I operation is anticipated to start in fourth quarter of 2017 and last for a duration of up to approximately 12 months, followed by a post-operational monitoring of 2 years. However, this will be evaluated as the program proceeds, and modifications may be requested.

It is expected that the average organic carbon dosing over the course of the 12-month Phase I program is 0.5% by volume. Based on the projected total recirculation volume of 21 million gallons of groundwater, the organic carbon demands for Phase I will be no more than 105,000 gallons of substrate (either molasses, EVO, or a combination of both). The actual dosing strength of these organic carbon substrates, the dosing durations per day (or per week), and the timing of molasses and EVO use will be determined based on monitoring observations.

Reagent flexibility is considered a key consideration for maximizing overall treatment during the IRM Program. While the carbon substrates above will serve as the primary reagents for use, other reagents are being included in this PBR to allow flexibility in the event that unique areas of the site are better suited to their application. Both FerroBlack®-H (a water based suspension of 7 to 8% by weight ferrous sulfide and 1 to 2% by weight sodium hydrosulfide) and $CaS_x$ (calcium

polysulfide) were used to achieve treatment during prior pilot test activities, and these reagents are retained for potential consideration during Phase I. $CaS_x$ could be delivered via the recirculation network as a soluble reagent for ISCR in select areas of Site 114 in lieu of, prior to, or following use of carbon substrate. In addition to these two reagents, ferrous sulfate heptahydrate ($FeSO_4$ x 7 $H_2O$) may also be used as a supplement to the carbon substrate source to provide additional iron and sulfide to further enhance Cr abiotic reduction mechanisms.

The planned IRM design consists of 35 injection and 7 extraction well positions. Each position is assumed to entail discrete screened intervals in both the intermediate and deep water-bearing units, resulting in 70 total injection wells and 14 extraction wells. However, up to 100 total injection wells and 25 total extraction wells may be installed if needed. Using hollow stem auger (HSA) drilling techniques (or similar equivalent drilling technologies), intermediate water-bearing zone wells will be constructed with 4-inch stainless steel, 10-slot, 20-foot screens at approximate depths between 20 to 40 feet below ground surface (bgs). Deep water-bearing zone wells will be constructed with 4-inch stainless steel, 10-slot, 20-foot screens between 45 to 65 feet bgs. Actual length of screen and screen size will be based on pre-design testing and field observations.

While a combined total injection and extraction rate of 17 gpm is expected to achieve organic carbon distribution within the southern area of Site 114 during the first 6-month period, extraction rates may be increased to maximize the total quantity of groundwater extracted and injected within system capabilities (40 gpm) and up to permit specifications. Over the first 6 months of operation, the Phase I design entails initiation of injection activities within the southern end of Site 114, followed by gradual northward shifts in operating wells during three, 8-week cycles. Injection wells may temporarily or permanently be converted to extraction wells to enhance hydraulic control, mass removal, and/or overcome aquifer heterogeneities. Following this first 6-month period, additional cycles are anticipated through the end of the planned 12-month operational period to replenish organic carbon substrates and address residual Cr concentrations.

In addition to the intermediate and deep groundwater treatment, a shallow water-bearing zone polishing treatment for Cr-impacted groundwater will be implemented in the vicinity of the current water treatment plant and pilot testing areas located in the north-western portion of the site. The shallow treatment will be completed as part of one injection event using temporary injection points. Injection points will be placed throughout an area estimated to be approximately 20,000 square feet ($ft^2$). Within this area, an estimated 70 total injection points will be installed on 20-foot on-center spacing. Using direct-push drilling methods, the injection points will be constructed using 1-inch PVC casing materials and a 10-foot 0.020-slot injection screen. The screen interval will be placed at depths between 5 to 15 feet bgs or with a terminal depth consistent with the observed top of the meadow mat. The selected carbon substrate for shallow water-bearing zone treatment is EVO. A total volume of up to 235,000 gallons of 2% EVO solution and up to approximately 5,000 gallons of as-delivered EVO material will be injected within the target shallow treatment area. During injection, multiple injection points/piezometers will be manifolded together for simultaneous injection.

The treatment of groundwater used for reinjection will be sufficient to achieve either 95% reduction of influent levels (e.g., primarily for Cr and Cr[VI]) or concentrations below the

applicable Ground Water Quality Standard (GWQS) values (e.g., for Cr, Cr[VI], and other compounds with historical detections) in the effluent of the water treatment plant, whichever is less stringent. A temporary permit-related ground water Classification Exception Area (CEA) is hereby established to allow the discharge of water containing Cr, Cr(VI), metals, volatile organic compounds (VOCs), and semi-volatile organic compounds (SVOCs) which may not be treated to levels below the GWQS by the water treatment plant prior to re-injection. The compounds other than Cr and Cr(VI) that were historically detected above the respective GWQS in the shallow, intermediate, and deep water-bearing zones are listed in the table below. Groundwater generated from the shallow water-bearing zone during soil excavation dewatering will be combined with groundwater extracted from the intermediate and deep water-bearing zones and treated with the water treatment plant. The permit-equivalent CEA comprises the entirety of the project area (Block 21501, Lots 16 through 20), and extends to a depth of 100 feet below ground surface.

## II. SYSTEM OPERATION AND MONITORING

The area of discharge shall be monitored for evidence of malfunction. Said evidence shall include, but is not limited to: injection solution observation at land surface, wet areas, ponding, odors, and elevated photoionization detector (PID) readings in the nearby work area or building. If encountered, appropriate controls and system modification will be implemented.

The discharge shall not cause any of the following negative impacts: adverse impact on the behavior of free product or the plume; adverse impacts to a water supply well or have a long term adverse impact on ground water quality; create an unpermitted discharge to any surface water of the State or violation of Surface Water Quality Standards; create a persistent standing, ponded or surface-flowing fluid condition; or cause adverse vapor intrusion to occur.

Pursuant to N.J.A.C. 7:14A-6.2(a)5 and 11, if free product in ground water, vapors or odors in any building, or any malfunction resulting in a potential impact to a receptor are detected and are a result of the discharge authorized by this approval, the discharger will immediately: (1) cease the discharge or make necessary adjustments to the discharge rate or system operation; and (2) repair or mitigate any negative impacts.

After completion of the discharge, the property returned to its previous condition, or as agreed to with property owner if the permittee is not the property owner. All UIC-Class V injection wells shall be properly abandoned in accordance with N.J.A.C. 7:14A-8.16(d)1 as applicable. The permittee will comply with any applicable provisions of the Additional Conditions Applicable to Class I, II, III and V UIC Permits of the NJPDES regulations, N.J.A.C. 7:14A-8.9, et seq. when UIC-Class V injection well units (i.e., the injection points) are used.

## III. GROUND WATER MONITORING REQUIREMENTS

The Permittee shall perform the following ground water sampling as was specified in the DGW proposal (including all addendums and modifications) for the purpose of complying with this Discharge to Ground Water Permit-By-Rule authorization.

Baseline Sampling, before injection:

Prior to the startup of Phase I operations, but following the installation of the remediation well network and new monitoring well locations, samples will be collected for baseline analysis to establish the starting conditions for IRM treatment performance review. In accordance with Table 1, baseline samples will be collected for TAL metals (total and dissolved); Cr(VI) (total and dissolved); key geochemical parameters (sulfate/sulfide and methane); total organic carbon (TOC), field parameters (pH, specific conductivity, dissolved oxygen (DO), oxidation-reduction potential (ORP), turbidity, and temperature); and depth to groundwater.

Baseline samples will be collected using the low-flow sampling method. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 micrometer (μm) filters in the field.

Operational and Treatment Monitoring, during the injections:

The operational monitoring program will be used to assess ongoing remedial system performance in support of guiding potential modifications to injection and extraction flow rates, recirculation well balancing, carbon dosing and timing, and to pre-emptively guide potential biofouling management and well redevelopment.

Operational monitoring will be performed at variable frequencies (weekly, biweekly, or monthly), as necessary, over the course of operation pursuant to Table 1. Measurements may be periodically performed more frequently than specified in Table

1 to support potential troubleshooting activities over the course of operation. Given the adaptive nature of the recirculation program and the sequencing of different groupings of injection and extraction wells during operation, it is anticipated that the operational sampling frequency of existing monitoring wells will be adapted over time. As an example, monitoring wells located within the southernmost area of Site 114 are most relevant for operational monitoring during the first step of recirculation activities. Following this initial 8-week period and the transition to more northerly injection wells, the frequency and parameter list of the initial monitoring locations may be reduced to maintain remedial efficiency, as applicable, subject to NJDEP approval. For the operational monitoring, analytical data and field parameter measurements for extracted and treated groundwater will be collected at operating extraction wells from sampling ports located at the wellheads or at the influent to the water treatment system.

Overall Phase I remedial performance will be documented via ongoing treatment monitoring during the 12-month IRM program. Sampling parameters will be collected to verify organic carbon distribution, assess the development of reduced geochemical groundwater conditions within the subsurface, and confirm corresponding declines in total Cr and Cr(VI). Evaluation of these parameters will confirm development of the subsurface reactive zone and will be used to guide carbon substrate dosing strength and frequency. This will enable treatment optimization and confirmation prior to transitioning the operating recirculation wells to subsequent steps. A summary of the analytical and field parameter measurements for treatment sampling is provided in Table 1.

Similar to the operational monitoring specifications, treatment monitoring parameters will be collected at specified frequency based on the relevance of a given parameter to operation and optimization activities. TOC and field parameter sampling is proposed most frequently (biweekly to monthly) to effectively gauge propagation of both carbon substrate and geochemical influence within the subsurface. Total Cr and Cr(VI) and select geochemical parameters (ferrous [dissolved] iron, dissolved manganese, sulfate) will be collected monthly to enable the collection of at least one to two samples between recirculation well steps. Methane sampling is also proposed, albeit less frequently, to confirm the overall extent of reduced groundwater conditions. Similar to the sampling frequency considerations presented for the operational monitoring program, select well locations or parameters may be collected more frequently for system optimization purposes, as applicable.

Treatment monitoring samples will be collected using the low-flow sampling method. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 μm filters in the field.

Post Treatment Sampling, after completion of injections:

> Following the 12-month Phase I operational program, post-treatment monitoring will be used to document overall Cr treatment performance, confirm the residual reactive zone reduction capacity (via residual TOC and reduced geochemistry species), and develop an appropriate data set to demonstrate ongoing natural attenuation of any residual total Cr and Cr(VI). Post-treatment sampling will be performed in accordance with Table 1.
>
> Treatment monitoring samples will be collected using the low-flow sampling method. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system – or containerized and disposed of off-site, as appropriate. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 µm filters in the field.
>
> Post-treatment sampling activities will be performed on a quarterly basis over a total duration of two years.

Pursuant to the Tech Regs, the Permittee shall measure ground water elevations at all sampled wells upon each sampling event and shall construct ground water flow maps with the water elevation data to document the direction of ground water flow. Any product observed, including sheen, shall be documented and the NJDEP shall be notified. If measurable product is observed, injections shall be suspended until all of the recoverable product is removed from the treatment area.

All sampling shall be performed as proposed and consistent with the methods specified in the most current edition of the Department's Field Sampling Procedures Manual. All samples shall be analyzed by a New Jersey Certified Laboratory certified for the methods being used to analyze groundwater samples. Analytical method MDLs shall be less than or equal to the ground water quality standards (N.J.A.C. 7:9C-1.7). Parameters determined in the field (pH, specific conductance, dissolved oxygen, temperature) are to be measured by a certified contractor or laboratory.

Comparison to the VI screening levels is necessary in order to monitor whether or not the discharge activities have the potential to cause VI issues within any nearby structures by means of adversely impacting the behavior of the ground-water contaminants (e.g., unexpected contaminant movement). If there are any exceedances of the VI screening levels caused by the authorized discharge, a VI evaluation shall be conducted of any potentially impacted structures.

Compliance with N.J.A.C. 7:26E-5.7(b) requires that the Permittee satisfy the post-injection ground water monitoring requirements that are set forth in this letter before applying for any Remedial Action Permit for Ground Water. If a Remedial Action Permit application is submitted before the required ground water sampling has been completed, the application will be denied.

Additionally, contingency compliance ground water sampling is required if ground water sampling results indicate that GWQS have been contravened because of the authorized discharge (e.g., the GWQS for sulfate is exceeded as a result of calcium polysulfide injection, or the GWQS for iron is

exceeded as a result of FerroBlack®-H injection), or that ground water quality has not returned to baseline conditions (when baseline concentrations are greater than GWQS) in the expected timeframe. Ground water sampling must continue until it can be demonstrated that the GWQS have been met or until the ground water quality has returned to baseline conditions. To demonstrate either of these conditions, a minimum of two consecutive ground water sampling events spaced far enough apart to account for seasonal fluctuations, must be conducted.

Furthermore, if the Permittee is planning to apply for a Ground Water Remedial Action Permit for Natural Attenuation in the future, and exceedances of the GWQS that are due to the discharge remain, those exceedances must be treated similarly to any other site related contaminants (i.e., a sufficient number of samples is required and a decreasing concentration trend must be evident) consistent with the Department's Remedial Action Permits for Ground Water Guidance.

## IV. REPORTING REQUIREMENTS AND INFORMATION SUBMITTALS

Details of the supplemental pre-design testing, well and system installation, system operation, and performance monitoring results associated with the IRM Phase I program will be documented as part of a quarterly technical status reports submitted to the NJDEP. These quarterly status reports will include succinct, high-level summaries of activities performed, data collected, adaptive steps taken to modify or optimize Phase I treatment, and an overview of activities planned for the subsequent quarter.

Succinct performance summary results will be submitted as part of quarterly status reports. All information, including a complete summary of the work performed under the PBR, a complete set of the data collected, a summary of data trends, an evaluation and interpretation of the data, and conclusions reached (as well as the QA/QC package specified at N.J.A.C. 7:26E-2.1(a)15) shall be submitted as part of the completion report following cessation active operation. All information shall be submitted to:

NEW JERSEY DEPARTMENT OF ENVIRONMENTAL PROTECTION
BUREAU OF CASE ASSIGNMENT & INITIAL NOTICE
MAILCODE 401-05H
P.O. BOX 420
TRENTON, NJ 08625-0420
ATTN: COPR

Consistent with N.J.A.C. 7:14A-2.11(a) and 6.2(a)14, within 90 days after initiation of the discharge, notify the Department of the "start date" of the discharge. To report this date, send an email to Tom.Cozzi@dep.nj.gov stating the start date of the discharge.

Consistent with N.J.A.C. 7:14A-2.11(a) and 6.2(a)14, any malfunctions or non-compliance should be reported by fax or telephone within 24 hours to Tom Cozzi of the Site Remediation Program at (609) 984-2905, and in writing within 7 days to the above address using the subject line "DGW Permit-by-Rule Compliance Report - COPR." Written submissions must include the facility name

and PI Number. Failure to report this information is a violation of N.J.A.C. 7:14A and the permit-by-rule.

If you have any questions or concerns, please contact Tom Cozzi of the Site Remediation Program at (609) 984-2905.

Sincerely,

Thomas Cozzi, Assistant Director
NJDEP Site Remediation Program, Office of the Assistant Commissioner

---

This memorandum (memo) presents the request for the proposed modification of the Groundwater Interim Remedial Measure (IRM) Phase I Design Permit-By-Rule (PBR) that was approved by the New Jersey Department of Environmental (NJDEP) on 21 September 2017 for the Garfield Avenue Group (GAG) Sites located in Jersey City, New Jersey. As discussed in the sections below, this IRM Phase I PBR modification requests adjustment of the current PBR approach for the following two planned site activities:

- The first of the planned site activities addresses IRM treatment in the shallow water-bearing zone. This PBR modification includes the proposed installation of two multipurpose wells that can be used for both extraction and injection operations within the vicinity of the one compliance well (GPS-MW1S) where both total chromium (Cr) and hexavalent chromium (Cr[VI]) have been detected in exceedance of the Groundwater Quality Standard (GWQS) of 70 micrograms per liter (µg/L) (**Figure 1**).
- The second activity is pilot testing of hydraulic fracturing techniques to emplace FerroBlack®-H (FerroBlack) chemical reductant and to enhance permeability to treat chromium in the low permeability transitional intermediate/deep water bearing zone below the meadow mat at Site 114. The pilot test(s) may be implemented in more than one phase, with the first pilot test scheduled to start in June 2019. This PBR modification includes potential injections over multiple phases during the fracturing process. Up to 10,000 gallons of FerroBlack and 10,000 gallons of potable water and clean sand slurry may be injected to open and maintain the fracture lenses.

## General Introduction

IRM Treatment in the Shallow Water-Bearing Zone

In accordance with the Phase I PBR, shallow water-bearing zone treatment using in situ anaerobic bioprecipitation (ISAB) was performed between December 28, 2017 and April 6, 2018 utilizing SRS®-SD (Terra Systems, Inc.) emulsified vegetable oil (EVO) injection into a network of temporary injection wells. These wells are spaced approximately 20-feet on-center throughout the target treatment area (**Figure 1**). The stock EVO product was diluted in the field with potable water from the on-site hot box. The shallow water-bearing zone treatment area was originally identified based on previous investigation data and was further refined prior to ISAB implementation using information obtained during the baseline monitoring event.

The shallow water-bearing zone treatment program is comprised of the following:

- 94 one-inch diameter remediation wells screened from approximately 5 to 15 ft below ground surface (bgs) in the shallow water-bearing zone.
- 9 previously existing two-inch diameter wells screened between approximately 5 and 16 ft bgs.
- 3 new one-inch diameter injection dose response monitoring wells screened between 5 and 15 ft bgs.
- A temporary mixing system including an above-ground water storage tank, the concentrated EVO storage totes, a transfer pump, an inline mixer, a flow regulating manifold, and temporary hose to connect the manifold to the individual well heads.

During the shallow water-bearing zone injection program, intermittent stoppages occurred due to inclement operational conditions (e.g., freezing conditions, saturated soils, and pooled water from precipitation events) and to minimize surfacing of the EVO solution at certain locations in the treatment area. Multiple injection wells were manifolded together to achieve simultaneous injection at 20 or more locations, and field observations dictated the need for modifications to the delivery program based on feasible injection flow rates at each location. Where select locations exhibited limited overall injectability, additional volume was delivered into adjacent or proximal points to optimize and balance shallow water-bearing zone EVO distribution.

The EVO dosing rate of about 2% by volume was increased to 4% by volume in accordance with the PBR modification request approved by NJDEP via email dated March 19, 2018. By the end of the injection program, a total of approximately 111,000 gallons of at least 2% EVO solution (approximately 3,020 gallons of as-delivered SRS®-SD EVO material) was injected in the treatment area. This volume was within the total maximum estimated volume allowed by the PBR of 235,000 gallons of at least 2% EVO solution (up to 5,000 gallons of as-delivered SRS®-SD EVO material).

Ongoing treatment monitoring in the shallow water-bearing zone treatment area has documented reductions in Cr(VI) levels to below the GWQS at all wells except GPS-MW1S. While Cr and Cr(VI) concentrations have declined, they are currently above the GWQS. In order to accelerate Cr treatment in the vicinity of GPS-MW1S, additional injections under the Phase I PBR are planned. To minimize the possibility of daylighting in the treatment area, reduce groundwater elevations in the shallow water-bearing zone, and enhance organic carbon substrate delivery, this Phase I PBR modification is being submitted to cover installation and operation of two new multipurpose extraction / injection wells (**Figure 1**).

Pilot Testing of Hydraulic Fracturing Techniques in the Transitional Intermediate/Deep Water-Bearing Zone

The first significant step in groundwater remediation of the intermediate and deep water-bearing zones at the GAG sites was implementation of the Phase I IRM that was conducted at Site 114 utilizing a combination of groundwater extraction and amended water reinjection with organic carbon substrate (molasses). The remedial strategy was designed to reduce Cr(VI) and precipitate trivalent chromium (Cr[III]) out of solution, establishing conditions conducive to continued attenuation of Cr(VI). Phase I of the injections occurred in 2018 and is continuing in 2019; the injections will be followed by post-treatment monitoring. Analysis of the results of the Phase I IRM revealed challenges with distribution of the reducing reagent for Cr precipitation in intervals of low permeability soils in the intermediate and deep water-bearing zones, which lessened the effectiveness of remediation.

In response to the challenges observed with reagent distribution during the Phase I GW IRM, hydraulic fracturing was identified as a potential technology to enhance the permeability of more massive low permeability soil intervals and increase reagent distribution. To test this method, a fracturing pilot test will be performed in one area of the Site in the transitioning intermediate to deep water-bearing zone. Given the heterogeneous nature of the subsurface at Site 114, additional areas of the Site may be considered for future applications based on the results of initial testing. The pilot test will evaluate the ability to create a network of fractures in the saturated geologic formation below the meadow mat in the low permeability unconsolidated soils to facilitate reagent delivery. The proposed initial location to conduct the pilot test is in the southwest area of the Site near Monitoring Well cluster 114-P1B-MW-103S and 114-P1B-MW-103D (Figure 2). This location was selected based on the known presence of low permeability soils, as evidenced during the Phase I GW IRM and the ability to use existing monitoring well infrastructure and Site data in this area of the Site.

The fracturing process is designed to facilitate reagent distribution in the treatment zone resulting in more expedient remediation of Cr(VI). Once fractures have been established to improve delivery and distribution, the introduction of FerroBlack facilitates reduction of Cr(VI) to Cr(III) which is subsequently filtered out by the formation as a precipitate. A proppant, such as sand, and a thickening or suspending agent (e.g. guar gum) maybe evaluated to maximize the ROI during FerroBlack injections.

**Proposed Modification for Shallow Zone Treatment**

Existing Phase I IRM injection wells and the two new multipurpose extraction / injection wells (**Figure 1**) are planned for use during the supplemental shallow water-bearing zone injection event. In addition to this modification, an update to the shallow water-bearing zone organic carbon substrate for ISAB is also proposed to include both molasses and EVO for subsurface injections. The two new multipurpose wells are proposed to allow operation as extraction locations in order to limit mounding influence and potential daylighting risk, enhance subsurface transport through the DGA, and support Cr removal.

The new extraction wells will be connected to existing Phase I IRM infrastructure for conveyance to the on-site water treatment plant. The existing mobile injection unit (MIU) will be used to dose dilute carbon source to select injection wells (shown in **Figure 1**) using above-grade conveyance piping. A potable water source is planned for injection use but treated groundwater may also be considered for water supply, as applicable. The carbon dosing will comprise approximately 2%

molasses solution or 2% EVO, or a 4% solution of combined organic carbon substrate. While injection volumes at individual wells are expected to vary based on achievable injection well flowrates and monitoring well breakthrough response, the total injection volume is expected to remain within the limits of the maximum volume approved in Phase I PBR.

**Installation of New Shallow Zone Multipurpose Remediation Wells**

The proposed new multipurpose wells will be installed by a union, New Jersey-licensed well driller and completed in accordance with the N.J.A.C. 7:9D. The drilling approach and well designs include the following:

- Drilling with a 6.25-inch inner diameter hollow stem auger (HSA) or using similar drilling technologies to the terminal depth of 15 feet below ground surface (bgs) or to the meadow mat (whichever is shallower) and screened from approximately 5 to 15 ft bgs.
- 10-foot, 4-inch Schedule 40 polyvinyl chloride (PVC) screens (10-slot with #0 sand pack)
- Schedule 40 PVC riser to approximately 3 feet above ground
- The wells will be finished with stick up mounts. Locking covers will be placed over each wellhead assembly.

During well completion, hydrated bentonite and grout will be used to seal the annulus to the surface. Final well completion determination will also account for surface elevation changes that may occur as part of regrading activities performed during site restoration activities. As applicable, protective bollards may also be installed to prevent well damage during the IRM.

A submersible pump will be used to withdraw the groundwater from the extraction wells and temporary, double-contained pipe will be used to convey the groundwater above-grade to an existing Phase I IRM extraction well vault for connection and conveyance to the water treatment system. Drawdown will be adjusted based on depth to water measurements in the operating extraction well(s) and in nearby monitoring wells.

For injection operations, the multipurpose wells will be equipped with temporary wellhead connections and above-grade conveyance hose to convey the injected recirculation water and carbon amendment to the well. Based on field and system performance observations, it is estimated that injection rates may vary between 0.1 to 1.0 gpm per well. Similar to extraction operations, injection wells may be operated at higher flow rates, depending on the nature of the soil formation and ability to receive fluids. Injections will also be attempted at existing shallow zone injection wells in the treatment area.

**Injection of FerroBlack Using Hydraulic Fracturing Wells**

The pilot test to evaluate hydraulic fracturing techniques to emplace a FerroBlack solution into low permeability zones and to enhance permeability in the transitional intermediate/deep water-bearing zones below the meadow mat at Site 114. The low permeability fracture zone will be selected using existing or proposed soil borings in the pilot test area, and hydraulic profiling and vertical aquifer profiling tests that will be completed during baseline sampling. The anticipated fracture zone is 40 to 60 feet below grade but will be selected from boring profiles during drilling. In addition, a monitoring well will be installed at the top of meadow mat (approximately 6 to 12 inches into the meadow mat) to assess the potential for effects of fracturing in the target treatment zone on the meadow mat above the fracture depth.

FerroBlack is a proprietary mixture of amorphous iron sulfide (mackinawite) particles with other compounds to create a site-specific beneficial chemical reductant, manufactured by Redox

Technology Group, LLC (d/b/a Redox Solutions), and that can be used to treat heavy metals such as Cr in soil and groundwater. A copy of the Safety Data Sheet for FerroBlack is included in Appendix A.

The hydraulic fracturing process will be designed to create multiple fractures or lenses at select depths in the target treatment zone below the meadow mat layer using high pressure fluids such as water and or a solution of FerroBlack. This process may be complemented by the addition of sand slurry to the fracturing fluid to act as a proppant to maintain the fracture lens post-injection, and will be field determined. A thickening agent (e.g. guar gum) may also be incorporated into the process. A copy of the Safety Data Sheet for guar gum is included in Appendix A.

The pilot test layout includes three fracture wells located radially around an existing monitoring well cluster (114-P1B-MW103S, MW-P1B-MW103D, and 114-P1-IRM-3). **Figure 2** shows the proposed pilot test layout and **Figure 3** shows the proposed pilot test area layout detail. The locations of the fracture wells are positioned at 15, 20, and 25 feet from the monitoring well cluster and will be used as a line of evidence to determine the optimum radius of influence during hydraulic fracturing and FerroBlack emplacement. The installation of the fracture wells includes the following:

- Either sonic or a combination of hollow stem auger/mud rotary drilling methods will be used to install three 4-inch diameter PVC fracture wells (FP-FW-01, -02, and -03) in approximately 8-inch diameter boreholes radially around the MW-103 cluster. The fracture wells will be grouted in place at least one week before fracturing commences.
    - The sonic drilling method results in a grouted, sealed borehole when complete. Permanent steel casings would not need to be installed using this technology as the sonic rig tooling would serve as the outer wall for placement of the grout before retracting the tooling. Although not needed, 10-inch outer steel casings may be installed to the meadow mat for each of the fracture wells.
    - Potentially, three permanent 8-inch steel casings may be installed in the meadow mat for the fracture wells. These steel casings would be installed if the combined hollow stem auger/mud rotary drilling methods were used to install the fracture wells. If installed, these casings would serve as outer (double) casings for fracture borings/wells through the meadow mat.
- At the selected fracture depth, a notch or a starting point will be created in the well casing to access the formation using a high pressure water jet to nucleate a fracture and create a lens for adding the FerroBlack to the formation. Down-well packers will be used to isolate the depth interval to be fractured and to emplace materials. Once the volume of FerroBlack has been injected, the fracture equipment will be moved to the next fracture interval and the process repeated.

**FerroBlack-H Dosing Design**

For the pilot test, the basis of design is to emplace the maximum volume of FerroBlack that could be emplaced in the equivalent of a 1/5 inch by 20-foot ROI. The estimated FerroBlack volume to be emplaced in the target treatment zone using the three fracture wells is approximately 2,000 gallons (approximately 20,000 pounds); however, up to 5,000 gallons of FerroBlack may be injected during the initial pilot test injection event. The FerroBlack will either be injected as a pure solution or mixed with potable water, and or clean sand slurry to act as a proppant and hold the

fracture lens open. For purposes of this PBR modification, it is assumed up to 5,000 gallons of potable water and/or 2,000 pounds of sand could potentially be mixed with the FerroBlack. The actual quantities of FerroBlack, water, and sand that will be injected will be field determined during the pilot test, and the goal will be to optimize the fracture extension and FerroBlack emplacement. The decision criteria will be based on the response of the formation and injected fluid leakoff through the fracture lens into the formation during fracture propagation. In addition, up to 500 pounds of guar gum potentially may be used during the hydraulic fracturing pilot test.

Based on the findings of the pilot test, additional pilot testing of hydraulic fracturing techniques to emplace FerroBlack may be performed in the same pilot test area, or in a second area with a different geology and Cr concentration. This PBR Modification requests permission to inject up to 10,000 gallons of FerroBlack with up to 10,000 gallons of potable water and/or 4,000 pounds of sand slurry, along with 1,000 pounds of guar gum.

**Treatment Monitoring and Reporting**

The treatment monitoring of the shallow water-bearing zone and reporting of the results will follow the procedures, frequency, and schedule presented in the approved Phase I PBR. These activities will be performed concurrently with the monitoring and reporting of the Phase I system for the treatment of intermediate and deep water-bearing zones.

In addition, monitoring of the effectiveness of the hydraulic fracturing process to maximize the emplacement of FerroBlack into the low permeability treatment zone located below the meadow mat layer will be completed using the following means and methods:

- As a potential line of evidence to assess ROI, heave monitoring to assess the radius of influence will be completed using an array of tiltmeters around one of the fracture wells during fracturing events and the injection of the FerroBlack solution.
- Measuring and recording injection pressures, nucleation pressure (breakdown pressure), maintenance pressure, volumes, flow rates, and duration will be conducted during the fracturing process.
- Monitoring of water levels, and groundwater field parameters (i.e., pH, specific conductivity, turbidity, dissolved oxygen [DO], oxidation reduction potential [ORP], temperature), and color will be conducted in seven existing monitoring wells (114-P1B-MW103S, 114-P1B-MW103D, 114-P1-IRM-3, 114-MW-4D, 114-P1-MW-1I/D, and 114-P1-IRM-7) and one new monitoring well (FP-MW01) installed in the meadow mat above the target treatment zone. These monitoring wells, shown in **Figure 2**, are located up-, down-, and side-gradient of the pilot test fracture network, and will be monitored before, during and end of the fracture program. **Table 1** shows the specifications for the pilot test monitoring wells.
- Monitoring the effectiveness of the FerroBlack injections by groundwater sampling and analysis of the seven existing monitoring wells in the pilot test area and one new well installed in the meadow mat, will be conducted before and two to four weeks after the hydraulic fracturing and FerroBlack emplacement is completed. The groundwater will be analyzed for total and dissolved Cr and iron, and sulfide[1]
- Soil logging and soil sampling to evaluate for visual evidence of fractures will be performed in the pilot test area based on evidence observed during FerroBlack emplacement. The soil logging and sampling will be conducted approximately one month following the hydraulic fracturing test.

- Pre- and post-fracture hydraulic permeability slug testing will be performed in two monitoring wells in the vicinity of the fracture wells. The monitoring wells will be selected after review of the HPT/VAP and soil boring logs. This will be used to evaluate beneficial changes that could be attributed to the fracture program. The hydraulic permeability slug testing will be conducted approximately one month following the hydraulic fracturing test.
- Pre- and post-fracture hydraulic permeability pump in testing, using potable water, will be performed over a period of several hours in one (pilot test area monitoring well in the vicinity of the fracture wells. The monitoring well will be selected after review of the HPT/VAP and soil boring logs. The hydraulic permeability pump in testing will be conducted approximately one month following the hydraulic fracturing test.

The findings from the hydraulic fracturing and FerroBlack emplacement pilot test will be documented in a pilot test technical memorandum.

Safety Data Sheets

# FerroBlack-H

Safety Data Sheet

according to Federal Register / Vol. 77, No. 58 / Monday, March 26, 2012 / Rules and Regulations

Date of issue: 06/14/2016 Revision date: 06/14/2016 Supersedes: 06/25/2015

## SECTION 1: Identification

### 1.1. Identification

Product form : Mixture

Trade name : FerroBlack-H

CAS No : 1317-37-9

Formula : FeS

Synonyms : Ferrous sulfide / Iron sulfide / Iron sulphide / Iron(II) sulfide / Ferrous sulfide / Iron sulfide / Iron sulphide / Iron(II) sulfide

### 1.2. Relevant identified uses of the substance or mixture and uses advised against

Use of the substance/mixture : Chemical used for the removal and/or sequestering of mercury. Also used as a mercury re-emission prevention chemical in wet flue gas desulfurization units.

### 1.3. Details of the supplier of the safety data sheet

Redox Technology Group, LLC
d/b/a Redox Solutions
1580 Research Way
Indianapolis, IN 46231

Company Contact: Jim Kissel
Telephone Number: (317) 660-6867 or (317) 412-3267

### 1.4. Emergency telephone number

CHEMTREC: (800) 424-9300

## SECTION 2: Hazard(s) identification

### 2.1. Classification of the substance or mixture

**GHS-US classification**

Skin corrosion/irritation Category 2 H315
Serious eye damage/eye irritation Category 2A H319

Full text of H statements : see section 16

### 2.2. Label elements

**GHS-US labeling**

Hazard pictograms (GHS-US) :

GHS07

Signal word (GHS-US) : Warning

Hazard statements (GHS-US) : H315 - Causes skin irritation
H319 - Causes serious eye irritation

Precautionary statements (GHS-US) : P264 - Wash hands thoroughly after handling
P280 - Wear eye protection, protective clothing, protective gloves
P302+P352 - If on skin: Wash with plenty of water
P305+P351+P338 - If in eyes: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing
P321 - Specific treatment (see Consult a doctor/medical service if you feel unwell on this label)
P332+P313 - If skin irritation occurs: Get medical advice/attention
P337+P313 - If eye irritation persists: Get medical advice/attention
P362+P364 - Take off contaminated clothing and wash it before reuse

### 2.3. Other hazards

**HMIS Classification:**
Health hazard: 0
Flammability: 0
Physical hazards: 0

**NFPA Rating:**
Health hazard: 1
Fire: 0
Reactivity Hazard: 0

**Inhalation** May be harmful if inhaled. May cause respiratory tract irritation.
**Skin** May be harmful if absorbed through skin. May cause skin irritation.
**Eyes** May cause eye irritation.
**Ingestion** May be harmful if swallowed.
**Other Hazards not contributing to the classification:** Generates toxic gas in contact with acid.

### 2.4. Unknown acute toxicity (GHS US)

Not applicable

## SECTION 3: Composition/Information on ingredients

### 3.1. Substance

Not applicable

### 3.2. Mixture

| Name | Product Identifier | % | GHS-US classification |
|---|---|---|---|
| Iron sulfide (FeS) | (CAS No) 1317-37-9 | 7 -11 | Not classified |
| Sodium Sulfide | (CAS No) 1313-82-2 | 0.1 - 1 | Acute Tox. 3 (Oral), H301 |

Full text of hazard classes and H-statements : see section 16

## SECTION 4: First aid measures

### 4.1. Description of first aid measures

First-aid measures general : Never give anything by mouth to an unconscious person. If you feel unwell, seek medical advice (show the label where possible).

First-aid measures after inhalation : Remove person to fresh air and keep comfortable for breathing. Remove victim to fresh air and keep at rest in a position comfortable for breathing. Immediately call a poison center or doctor/physician.

First-aid measures after skin contact : Remove/Take off immediately all contaminated clothing. Rinse skin with water/shower. If skin irritation occurs: Get medical advice/attention.

First-aid measures after eye contact : Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing. Immediately call a doctor/physician. If eye irritation persists: Get medical advice/attention.

First-aid measures after ingestion : Rinse mouth. Do NOT induce vomiting. Immediately call a poison center or doctor/physician. Call a poison center/doctor/physician if you feel unwell.

### 4.2. Most important symptoms and effects, both acute and delayed

Symptoms/injuries : Causes skin and eye irritation.

Symptoms/injuries after skin contact : Irritation.

Symptoms/injuries after eye contact : Causes serious eye damage. Eye irritation.

### 4.3. Indication of any immediate medical attention and special treatment needed

Treat symptomatically.

## SECTION 5: Firefighting measures

### 5.1. Extinguishing media

Suitable extinguishing media : Foam. Dry powder. Carbon dioxide. Water spray. Sand.

Unsuitable extinguishing media : Do not use a heavy water stream.

### 5.2. Special hazards arising from the substance or mixture

Reactivity : Corrosive vapors.

### 5.3. Advice for firefighters

Firefighting instructions : Use water spray or fog for cooling exposed containers. Exercise caution when fighting any chemical fire. Prevent fire-fighting water from entering environment.

Protection during firefighting : Do not enter fire area without proper protective equipment, including respiratory protection. Do not attempt to take action without suitable protective equipment. Self-contained breathing apparatus. Complete protective clothing.

## SECTION 6: Accidental release measures

### 6.1. Personal precautions, protective equipment and emergency procedures

#### 6.1.1. For non-emergency personnel

Emergency procedures : Ventilate spillage area. Evacuate unnecessary personnel. Avoid contact with skin and eyes.

#### 6.1.2. For emergency responders

Protective equipment : Do not attempt to take action without suitable protective equipment. Equip cleanup crew with proper protection. For further information refer to section 8: "Exposure controls/personal protection".

Emergency procedures : Ventilate area.

### 6.2. Environmental precautions

Avoid release to the environment. Prevent entry to sewers and public waters. Notify authorities if liquid enters sewers or public waters.

### 6.3. Methods and material for containment and cleaning up

Methods for cleaning up : Take up liquid spill into absorbent material. Soak up spills with inert solids, such as clay or diatomaceous earth as soon as possible. Collect spillage. Store away from other materials.

Other information : Dispose of materials or solid residues at an authorized site.

### 6.4. Reference to other sections

See Heading 8. Exposure controls and personal protection. For further information refer to section 13.

## SECTION 7: Handling and storage

### 7.1. Precautions for safe handling

Precautions for safe handling : Ensure good ventilation of the work station. Wash hands and other exposed areas with mild soap and water before eating, drinking or smoking and when leaving work. Provide good ventilation in process area to prevent formation of vapor. Do not breathe dust, fume, gas, mist, spray, vapors. Avoid contact during pregnancy/while nursing. Avoid contact with skin and eyes. Wear personal protective equipment.

Hygiene measures : Wash hands thoroughly after handling. Wash contaminated clothing before reuse. Do not eat, drink or smoke when using this product. Always wash hands after handling the product.

### 7.2. Conditions for safe storage, including any incompatibilities

Technical measures : Comply with applicable regulations.

Storage conditions : Keep only in the original container in a cool, well ventilated place away from : Ignition sources, Incompatible materials. Keep container closed when not in use. Store in a well-ventilated place. Keep cool.

Incompatible products : Strong bases. Strong acids.

Incompatible materials : Sources of ignition. Direct sunlight.

## SECTION 8: Exposure controls/personal protection

### 8.1. Control parameters

| **FerroBlack-H (1317-37-9)** | | |
|---|---|---|
| ACGIH | ACGIH TWA (mg/m³) | 1.4 mg/m³ |
| ACGIH | ACGIH TWA (ppm) | 1 ppm |
| ACGIH | ACGIH STEL (mg/m³) | 7 mg/m³ |
| ACGIH | ACGIH STEL (ppm) | 5 ppm |

| **Iron sulfide (FeS) (1317-37-9)** |
|---|
| Not applicable |

| **Sodium sulfide (1313-82-2)** |
|---|
| Not applicable |

### 8.2. Exposure controls

| | |
|---|---|
| Appropriate engineering controls | : Ensure good ventilation of the work station. |
| Personal protective equipment | : Avoid all unnecessary exposure. |
| Hand protection | : Wear protective gloves. |
| Eye protection | : Chemical goggles or face shield. Safety glasses. |
| Skin and body protection | : Wear suitable protective clothing. |
| Respiratory protection | : Wear appropriate mask. |
| Environmental exposure controls | : Avoid release to the environment. |
| Other information | : Do not eat, drink or smoke during use. |

## SECTION 9: Physical and chemical properties

### 9.1. Information on basic physical and chemical properties

| | |
|---|---|
| Physical state | : Liquid |
| Appearance | : Black liquid with visible suspended solids. |
| Color | : Black |
| Odor | : Rotten eggs |
| Odor threshold | : No data available |
| pH | : 11.5 - 12.8 |
| Melting point | : Not applicable |
| Freezing point | : No data available |
| Boiling point | : No data available |
| Flash point | : No data available |
| Relative evaporation rate (butyl acetate=1) | : No data available |
| Flammability (solid, gas) | : Non flammable. |
| Vapor pressure | : No data available |
| Relative vapor density at 20 °C | : No data available |

### 9.2. Other information

No additional information available

## SECTION 10: Stability and reactivity

### 10.1. Reactivity

Acidic vapors.

### 10.2. Chemical stability

Not established.

### 10.3. Possibility of hazardous reactions

Contact with acids liberates toxic gas.

### 10.4. Conditions to avoid

Direct sunlight. Extremely high or low temperatures.

### 10.5. Incompatible materials

Acids will cause the release of highly toxic Hydrogen Sulfide. Reacts violently with diazonium salts. Ferrous sulfide(s) solution is not compatible with copper, zinc, aluminum or their **alloys** (i.e. bronze, brass, galvanized metals, etc.). Corrosive to steel above 150º F (65.5º C). These materials of construction should not be used in handling systems or storage containers for this product.

### 10.6. Hazardous decomposition products

Hazardous decomposition products formed under fire may include sulfur oxides, iron oxides.

## SECTION 11: Toxicological information

### 11.1. Information on toxicological effects

Acute toxicity : Not classified

| Sodium Sulfide (113-82-2) | |
|---|---|
| LD50 oral rat | 208 mg/kg |
| ATE US (oral) | 208.000 mg/kg body weight |
| LD50 dermal rabbit | < 340 mg/kg |
| ATE US (dermal) | 300.000 mg/kg body weight |

Skin corrosion/irritation : Causes skin irritation.
pH: 11.5 - 12.8

Serious eye damage/irritation : Causes eye irritation.
pH: 11.5 - 12.8

Respiratory or skin sensitization : Not classified

Germ cell mutagenicity : Not classified

Carcinogenicity : Not classified

Reproductive toxicity : Not classified

Specific target organ toxicity (single exposure) : Not classified

Specific target organ toxicity (repeated exposure) : Not classified

Aspiration hazard : Not classified

Potential Adverse human health effects and symptoms : Based on available data, the classification criteria are not met.

Symptoms/injuries after skin contact : Irritation.

Symptoms/injuries after eye contact : Causes eye irritation.

## SECTION 12: Ecological information

### 12.1. Toxicity

Ecology - general : The product is not considered harmful to aquatic organisms or to cause long-term adverse effects in the environment.

| FerroBlack-H (1317-37-9) | |
|---|---|
| LC50 fish 1 | > 10000 mg/l Mosquito fish |

| Sodium Sulfide (1313-82-2) | |
|---|---|
| LC50 fish 1 | 7.7 - 29.1 mg/l (Exposure time: 96 h - Species: Poecilia reticulata) |
| EC50 Daphnia 1 | 2.1 mg/l (Exposure time: 48 h - Species: Daphnia magna) |

### 12.2. Persistence and degradability

| FerroBlack-H (1317-37-9) | |
|---|---|
| Persistence and degradability | Not established. |

### 12.3. Bioaccumulative potential

| FerroBlack-H (1317-37-9) | |
|---|---|
| Bioaccumulative potential | Not established. |

| Sodium Sulfide (16721-80-5) | |
|---|---|
| Log Pow | -3.5 (at 25 °C) |

### 12.4. Mobility in soil

No additional information available

### 12.5. Other adverse effects

Effect on the global warming : No known effects from this product.

GWPmix comment : No known effects from this product.

Other information : Avoid release to the environment.

## SECTION 13: Disposal considerations

### 13.1. Waste treatment methods

Waste treatment methods : Dispose of contents/container in accordance with licensed collector's sorting instructions.

Waste disposal recommendations : Dispose of contents/container to hazardous or special waste collection point, in accordance with local, regional, national and/or international regulation.

Ecology - waste materials : Avoid release to the environment.

## SECTION 14: Transport information

**Department of Transportation (DOT)**

In accordance with DOT

Not Regulated

**Transport by sea**

Not Regulated

**Air transport**

Not Regulated

## SECTION 15: Regulatory information

### 15.1. US Federal regulations

| Iron sulfide (FeS) (1317-37-9) |
|---|
| Listed on the United States TSCA (Toxic Substances Control Act) inventory |

| Sodium Sulfide (1313-82-2) |

# Safety Data Sheet

## SECTION 1: IDENTIFICATION

**Product Identifier**
**Trade Name:** **G150 Guar Gum**

**Recommended Use of the Chemical and Restrictions on Use**
**Product Use**:
**Uses Advised Against:** None identified

**Manufacturer/Supplier:** **Rantec Corporation**
**Address:** 17 Kukuchka Lane
Ranchester, WY 82839

**Phone Number:** (307) 655-9565
**Fax Number:** (307) 655-9528
**e-mail:** rantec@ranteccorp.com

**SDS Date of Preparation**: December 15, 2014

## SECTION 2: HAZARDS IDENTIFICATION

**GHS Classification:**
Combustible Dust
Respiratory Sensitizer Category 1

**Label Elements:**
Danger!

May form combustible dust concentrations in air.
May cause allergy or asthma symptoms or breathing difficulties if inhaled.

Avoid breathing dust or fume.
In case of inadequate ventilation, wear respiratory protection.
IF INHALED: If breathing is difficult, remove victim to fresh air and keep at rest in a position comfortable for breathing.
If experiencing respiratory symptoms: Remove victim to fresh air and call POISON CENTER or doctor.
Dispose of contents in accordance with local, regional and national regulations.

**Other Hazards:** None

## SECTION 3: COMPOSITION/INFORMATION ON INGREDIENTS

| Chemical Name | CAS# | % |
|---|---|---|
| Guar Gum | 9000-30-0 | 100 |

## SECTION 4: FIRST AID MEASURES

**Description of First Aid Measures**

**Eye:** Flush thoroughly with water. If irritation persists get medical attention.

**Skin:** No first aid should normally be needed. Wash exposed skin with soap and water after use. If irritation or rash develops, get medical attention. Use skin lotion if dryness occurs.

**Inhalation:** If symptoms of irritation or allergy develop, remove person from source of exposure to fresh air. Get immediate medical attention if asthmatic symptoms develop.

**Ingestion:** DO NOT INGEST. While this product is not toxic by ingestion, swallowing small amounts could cause complete blockage of the mouth, pharynx, trachea, esophagus and/or gastrointestinal system which may cause choking, suffocation and/or other life threatening medical conditions. Get medical attention immediately.

**Most Important symptoms and effects, both acute and delayed:**

May cause mechanical eye and skin irritation. Inhalation of dust may cause nose and throat irritation, coughing and sneezing. Inhalation may cause sensitization and difficulty breathing. Ingestion may cause gastric upset and nausea.

**Indication of any immediate medical attention and special treatment needed:** If inhaled and causes allergic reaction, seek prompt medical attention. Seek immediate medical attention if any amount is ingested.

## SECTION 5: FIRE FIGHTING MEASURES

**Extinguishing Media:**

Use water fog, dry chemical, carbon dioxide or foam. Do not use solid water jet as that may create a dust cloud that can present an explosion hazard. Guar gum is very slippery when wet.

**Specific Hazards Arising from the Chemical**

High concentrations of dust suspended in air may present a potential explosion hazard. Settled dust presents a fire hazard. Re-suspension of the dust into the air by vibration, traffic, material handling, etc. in high concentrations in the presence of an ignition source could result in a dust explosion. Minimize the generation and accumulation of dust. Slip hazard: product is very slippery when wet.

**Hazardous Decomposition Products:** Combustion may produce oxides of carbon and nitrogen.

**Special Protective Equipment and Precautions for Fire-Fighters:**

Firefighters should wear positive pressure self-contained breathing apparatus and full protective clothing.

## SECTION 6: ACCIDENTAL RELEASE MEASURES

**Personal Precautions, Protective Equipment and Emergency Procedures:**

Wear appropriate protective equipment. Avoid creating and breathing dust. Eliminate ignition

sources. Combustible Dust in Industry: Preventing and Mitigating the Effects of Fire and Explosions. Safety and Health Information Bulletin. SHIB 07-31-2005; updated 11-12-2014. https://www.osha.gov/dts/shib/shib073105.html

**Environmental Precautions:**

Avoid unintentional release to the environment.

**Methods and Material for Containment and Cleaning Up:**

Do not use water or water based solvents. Collect dry and in a manner to minimize the generation of airborne dust or vacuum with a high vacuum cleaner. If a vacuum is used, explosion proof equipment is required. Non-sparking tools should be used. Dust deposits should not be allowed to accumulate on surfaces, as these may form an explosive mixture if they are released into the atmosphere in sufficient concentrations. Avoid dispersal of dust in the air (i.e., clearing dust surfaces with compressed air.)

**Reference to Other Sections:**

Refer to Section 8 for protective equipment. Refer to Section 13 for disposal guidance.

## SECTION 7: HANDLING AND STORAGE

**Precautions for Safe Handling**:

Avoid contact with eyes and clothing. Avoid creating and breathing dusts. Wear protective clothing and equipment as described in Section 8. Use only with adequate ventilation. Wash thoroughly with soap and water after handling. Minimize the generation and accumulation of dust. Keep dust away from open flames, hot surfaces and sources of ignition. Follow good housekeeping practices to keep surfaces, including areas overhead such as piping, drop ceilings, ductwork, etc. free from settled dust. Dry powders can build static electricity charges when subjected to friction of transfer and in mixing operations. Provide adequate precautions, such as electrical grounding and bonding, or inert atmospheres.

Empty containers retain product residues. Follow all SDS precautions in handling empty containers.

**Conditions for Safe Storage, Including any Incompatibilities**

Keep containers closed when not in use.

## SECTION 8: EXPOSURE CONTROLS/PERSONAL PROTECTION

**Exposure Limits:**

| Chemical Name | Exposure Limits |
|---|---|
| Guar Gum (as PNOR) | 5 mg/m3 TWA OSHA PEL (respirable), 15 mg/m3 TWA (total dust) |

**Note:** The OSHA limits may not adequately protect workers from respiratory sensitization. Exposure levels should be maintained as low as possible for the workers' protection.

Refer to local regulations for specific requirements.

**Exposure Controls:**

**Engineering Controls:** Use explosion proof local exhaust ventilation as needed to maintain exposure concentrations below the recommended limits.
**Eye and Face:** Follow facility requirements. Dust goggles recommended for dusty conditions.
**Skin:** None required. Work gloves may be used to protect against mechanical irritation.
**Respiratory:** If the concentrations exceed the Threshold Value Limit (TLV), a NIOSH approved dust respirator, supplied air respirator or self-contained breathing apparatus is recommended. Select appropriate respiratory protection for respirable particulates based on consideration of the airborne workplace concentrations and duration of exposure. Select and use respirators in accordance with 29 CFR 1910.134, ANSI Z88.2, the NIOSH Respirator Decision Logic and good

industrial hygiene practice.
**Protective Clothing:** Appropriate protective clothing as needed to minimize skin contact.
**Work Hygienic Practices**: Wash thoroughly after handling.

## SECTION 9: PHYSICAL AND CHEMICAL PROPERTIES

| | |
|---|---|
| **Physical State:** Solid | **Appearance:** Creamy white powder |
| **Odor:** Bean-like odor | **Odor Threshold**: Not applicable |
| **pH:** Not applicable | **Relative Density:** Not applicable |
| **Boiling Point:** Not applicable | **Melting Point:** Decomposes |
| **Vapor Pressure:** Not applicable | **Water Solubility:** complete solubility |
| **Vapor Density:** Not applicable | **Evaporation Rate:** Not applicable |
| **Viscosity**: Not applicable | **Pour Point**: Not applicable |
| **Flash Point:** Not applicable | **Flammable Limits: LEL:** 0.04 oz/cf |
| **Autoignition Temperature**: None | **Flammable Limits: UEL:** Not applicable |
| **Percent Volatile**: Not applicable | **Flammability (solid/gas):** Not applicable |
| **Partition Coefficient: n-octanol/water:** Not applicable | **Decomposition Temperature:** None |
| **Explosive Properties:** Combustible dust | **Oxidizing Properties:** None |

## SECTION 10: STABILITY AND REACTIVITY

**Reactivity:** Not reactive.

**Chemical Stability:** Stable under normal conditions.

**Possibility of Hazardous Reactions:** Reactions with strong oxidizers may generate heat.

**Conditions to Avoid:** Keep away ignition sources. Combustible Dust in Industry: Preventing and Mitigating the Effects of Fire and Explosions. Safety and Health Information Bulletin. SHIB 07-31-2005; updated 11-12-2014. https://www.osha.gov/dts/shib/shib073105.html

**Incompatible Materials:** Avoid strong acids and oxidizing agents.

**Hazardous Decomposition Products:** Thermal decomposition may produce carbon and nitrogen oxides.

## SECTION 11: TOXICOLOGICAL INFORMATION

**Information on Toxicological Effects:**

**Eye Contact:** Contact may cause irritation based on studies with laboratory animals.

**Skin Contact:** Contact may cause dryness.

**Inhalation:** Inhalation of dust may cause irritation of the nose, throat and respiratory passages. Symptoms include coughing, sore throat, nasal congestion, sneezing wheezing and shortness of breath. May cause allergic reaction in susceptible individuals.

**Ingestion:** Ingesting small amounts could cause complete blockage of the mouth, pharynx, trachea, esophagus and/or gastrointestinal system which may cause choking, suffocation and/or other life threatening medical conditions.

**Acute Toxicity Data**:
Guar Gum: Oral rat LD50: 9.4g/kg

Guar gum is a natural food additive, although direct use in powder or pill form is banned by the FDA due to the risk of respiratory or gastrointestinal blockage.

**Chronic Health Effects**: Prolonged overexposure to any nuisance dust may cause lung injury. Symptoms include cough, shortness of breath and reduced pulmonary function.

**Germ Cell Mutagenicity:** No data available. This product is not expected to cause mutagenic activity.

**Carcinogenicity:** None of the components of this product are listed as carcinogens or suspected carcinogens by OSHA, IARC or NTP.

**Developmental / Reproductive Toxicity**: No data available. This product is not expected to cause adverse effects on reproduction or development.

**Specific Target Organ Toxicity (Single Exposure)**: No data available.

**Specific Target Organ Toxicity (Repeated Exposure)**: Prolonged overexposure to any nuisance dust may cause lung injury. Symptoms include cough, shortness of breath and reduced pulmonary function.

## SECTION 12: ECOLOGICAL INFORMATION

**Toxicity:**
No data available. This product is not expected to be toxic to aquatic organisms.

**Persistence and Degradability:**
No data available.

**Bioaccumulative Potential:**
Not expected to bioaccumulate.

**Mobility in Soil:**
No mobility in soil is expected.

**Other Adverse Effects:** None known.

## SECTION 13: DISPOSAL INFORMATION

**Waste Treatment Methods**

**Disposal Method**: Dispose in accordance with all local, state and federal regulations.
**Empty Container**: No special handling or disposal is required.
**General Comments**: It is the responsibility of the user of this product to characterize wastes generated to determine if the waste meets the definition of hazardous waste. The product uses, transformations, synthesis, mixtures, etc., may render the resulting end product subject to regulation.

## SECTION 14: TRANSPORT INFORMATION

| | UN Number | UN Proper Shipping Name | Transport Hazard Class(s) | Packing Group | Environmental Hazards |
|---|---|---|---|---|---|
| **US DOT** | None | Not regulated | None | None | Not applicable |
| **EU ADR/RID** | None | Not regulated | None | None | Not applicable |
| **IMDG** | None | Not regulated | None | None | Not applicable |

**Special Precautions for User:** None

## SECTION 15: REGULATORY INFORMATION

**Safety, Health and Environment Regulations:**

**US Regulations:**
**EPA SARA 311/312 Hazard Classification**: Fire Hazard, Acute Health

**EPA SARA 313**: This Product Contains the Following Chemicals Subject to Annual Release Reporting Requirements Under SARA Title III, Section 313 (40 CFR 372): None

**Protection Of Stratospheric Ozone**: This product is not known to contain or to have been manufactured with ozone depleting substances as defined in 40 CFR Part 82, Appendix A to Subpart A.

**CERCLA Section 103**: This product is not subject to CERCLA spill reporting requirements. Many states have more stringent release reporting requirements. Report spills when required under federal, state and local regulations.

**California Proposition 65**: This product is not known to contain chemicals regulated under Proposition 65.

**Canadian Regulations:**
**Canadian WHMIS**: D-2-A
This product has been classified in accordance with the hazard criteria in the CPR and the SDS contains all the information required by the CPR.

**Chemical Inventories:**
**US TSCA** All of the components of this material are listed on the Toxic Substances Control Act (TSCA) Chemical Substances Inventory or are exempt.
**Canadian CEPA**: All of the components are listed on the Canadian DSL or are exempt.
**Australia:** All of the components are listed on the AICS inventory or are exempt.
**China:** All the components are listed on the Chinese chemical inventory or are exempt.
**Philippines:** All the components are listed in the Philippine Inventory.
**New Zealand:** All of the components are listed on the New Zealand Inventory of Chemicals.
**Korea:** All of the components are listed on the Korean Existing Chemicals Inventory
**Japan**: All the components are listed on the Japan Inventory of existing chemicals.

## SECTION 16: OTHER INFORMATION

**NFPA Ratings:**
Health: 1 Flammability: 2 Reactivity: 0

**HMIS Ratings:**
Health: 1 Flammability: 2 Reactivity: 0

**SDS Date of Preparation/Revision**: December 15, 2014

**Revision History**: Conversion to GHS format. Changes in all Sections.

Cc: "Overmyer, Jody" <overmyer@ppg.com>, "Feinberg, Richard [C]" <feinberg@ppg.com>, "Flanders, Cullen" <Cullen.Flanders@arcadis.com>, "Hellerich, Lucas" <Lucas.Hellerich@aecom.com>, "Horst, John" <John.Horst@arcadis.com>
Subject: RE: PPG Site 114 - PBR Modification Request

Hello all,

On behalf of PPG, Arcadis has submitted an updated proposed modification of the Groundwater Interim Remedial Measure (IRM) Phase I Design Permit-By-Rule (PBR) that was approved by the New Jersey Department of Environmental (NJDEP) on 21 September 2017 for the Garfield Avenue Group (GAG) Sites located in Jersey City. This Phase I PBR modification covers installation and operation of two new multipurpose extraction / injection wells near GPS-MW1S. In addition to this modification, an update to the shallow water-bearing zone organic carbon substrate for ISAB is also proposed to include both molasses and EVO for subsurface injections. The carbon dosing will comprise approximately 2% molasses solution or 2% EVO, or a 4% solution of combined organic carbon substrate.

The proposed modification also requests pilot testing of hydraulic fracturing techniques in the transitional intermediate/deep water-bearing zone. The pilot test proposes to evaluate hydraulic fracturing techniques to emplace a FerroBlack solution into low permeability zones and to enhance permeability in the transitional intermediate/deep water-bearing zones below the meadow mat at Site 114. The anticipated fracture zone is 40 to 60 feet below grade but will be selected from boring profiles during drilling. The pilot test layout includes three fracture wells (FP-FW-01, -02, and -03) located radially around existing monitoring well cluster MW-103 (114-P1B-MW103S, MW-P1B-MW103D, and 114-P1-IRM-3). The three 4-inch diameter PVC fracture wells would be installed in approximately 8-inch diameter boreholes. Either sonic or a combination of hollow stem auger/mud rotary drilling methods will be used. If the combined hollow stem auger/mud rotary drilling methods are used, three 8 steel casings would be Installed in the meadow mat serve as outer (double) casings. If sonic drilling methods are used, permanent steel casings would not necessarily need to be installed, but 10-inch outer steel casings may be installed to the meadow mat.

A high pressure water jet would be used to nucleate a fracture and create a lens for adding the FerroBlack to the formation. The estimated FerroBlack volume to be emplaced in the target treatment zone using the three fracture wells is approximately 2,000 gallons (approximately 20,000 pounds); however, up to 5,000 gallons of FerroBlack may be injected during the initial pilot test injection event. The FerroBlack will either be injected as a pure solution or mixed

with potable water, and or clean sand slurry to act as a proppant and hold the fracture lens open. For purposes of this PBR modification, it is assumed up to 5,000 gallons of potable water and/or 2,000 pounds of sand could potentially be mixed with the FerroBlack. In addition, up to 500 pounds of guar gum potentially may be used during the hydraulic fracturing pilot test.

Based on the findings of the pilot test, additional pilot testing of hydraulic fracturing techniques to emplace FerroBlack may be performed in the same pilot test area, or in a second area with a different geology and Cr concentration. This PBR Modification requests permission to inject up to 10,000 gallons of FerroBlack with up to 10,000 gallons of potable water and/or 4,000 pounds of sand slurry, along with 1,000 pounds of guar gum.

The Department hereby approves the proposed PBR modification request. The injection and monitoring activities must be performed as proposed in the 22 May 2019 “Discharge to Groundwater Permit-by-Rule Modification Request”.

Subject: [EXTERNAL] FW: PPG Site 114 - PBR Modification Request

All –

In response to a question from Dave on drilling methodology for one portion of the Site 114 Phase I IRM PBR Modification Request submitted last Thursday, minor revisions to last week’s document were made to provide additional flexibility for drilling during the hydraulic pilot test. These were submitted in an updated version yesterday and is attached here to incorporate the broader distribution group.

Subject: RE: PPG Site 114 - PBR Modification Request

Dave –

In response to your question below and our phone conversation last week, attached is the updated Phase I IRM PBR Modification request for both the shallow zone activities and the hydraulic fracturing pilot test. As we discussed, additional detail has been added to page 5 of this document to reflect the considerations for either sonic or HSA/mud rotary mud rotary drilling and the specifications around when an additional outer casing is included to isolate the meadow mat. This provides increased flexibility for pilot test planning and ultimately enables selection of the appropriate methodology.

Please let us know if you have further questions. Thanks.

Matt

Subject: RE: PPG Site 114 - PBR Modification Request

Matthew,

Not 10 minutes before I received this email, I got a call from AECOM about a "hydraulic fracturing pilot test" at this site, where steel casing was not proposed. Although they checked with our Bureau of Well Permitting and Water Allocation, and were told it would be okay, they seemed worried about this. I agreed. Right after the call, I received this proposal and see you are proposing steel casing. Has there been some change? I also see that sonic drilling is proposed, and Well Permitting allows sonic drilling to omit the steel secondary casing since the sonic drill protects the borehole and achieves a good grout seal. Am I misunderstanding something? Or did PPG review an earlier draft? How did AECOM get he idea that steel secondary casing down to meadow mat was being omitted?

Subject: [EXTERNAL] PPG Site 114 - PBR Modification Request

David –

On behalf of PPG, Arcadis and AECOM have prepared the attached request to modify the PBR Discharge Authorization approved by NJDEP for Garfield Avenue Group Site 114 in Jersey City, Hudson County, New Jersey. The proposed modification to the existing PBR includes: 1) the installation of several new multipurpose wells to support ongoing treatment in the shallow water-bearing zone; and 2) the implementation approach for pilot testing hydraulic fracturing to enhance permeability and reagent delivery in the intermediate and deep water-bearing zones. Both approaches are consistent with discussions during the February 6, 2019 Site 114 Groundwater IRM Status meeting in Jersey City.

Please let us know if you agree with these proposed modifications, or if you have any questions.

Regards,
Matt Schnobrich

**New Jersey Department of Environmental Protection**
Site Remediation and Waste Management Program

# DISCHARGE TO GROUND WATER (DGW) PERMIT-BY-RULE AUTHORIZATION REQUEST

☐ LSRP ☐ Subsurface Evaluator (UHOT)

**Date Stamp (For Department use only)**

## SECTION A. SITE NAME AND LOCATION

Site Name: Garfield Avenue Site 113 and Former Halladay Street Gas Works

AKAs:

Street Address: 900 Garfield Avenue

Municipality: Jersey City (*Township, Borough or City*)

County: Hudson Zip Code: 07305

Program Interest (PI) Number(s): G000008791

Case Tracking Number(s) for this submission:

Municipal block(s) and lot(s) where the **proposed discharge(s)** would occur:

Block # 21501 Lot #(s) 16, 17, 18, 19, 20 Block # Lot #(s)

Block # Lot #(s) Block # Lot #(s)

## SECTION B. FEE AND DISCHARGE INFORMATION

DGW Proposal Review Fee ..... $350.00

**Discharge Type** *(check all that apply)*

☒ Discharge of Recovered Ground Water

Will the discharge be a result of dewatering only? ..... ☐ Yes ☐ No

☒ Discharge that is part of an *In situ* Remediation

☐ Discharges other than those above *(see instructions for more information)*

**Facility Type** *(check all that apply)*

☒ Underground Injection Control (UIC) facility (i.e., any type of injection)

☐ Non-UIC (e.g., surface application) *(see instructions for more information)*

**Attach a Discharge to Ground Water Proposal to this form** *(see instructions)* See attached CD

## SECTION C. PUBLIC NOTICE PROVISIONS *(Does not apply to residential heating oil tank cases)*

Is the proposed discharge lasting greater than 180 days? ..... ☒ Yes ☐ No

If "Yes," attach a copy of the public notice written as you intend it to be published. *(see instructions)* See attached CD, Appendix A

## SECTION D. SITE USE AND GROUND WATER CLASSIFICATION

**Current Site Use** *(check all that apply)*

☐ Industrial ☐ Agricultural
☐ Residential ☐ Park or recreational use
☐ Commercial ☒ Vacant
☐ School or child care ☐ Government
☐ Other

**Intended Future Site Use** *(check all that apply)*

☐ Industrial ☐ Park or recreational use
☐ Residential ☐ Vacant
☐ Commercial ☐ Government
☐ School or child care ☒ Future site use unknown

What is the ground water classification for this site as per N.J.A.C. 7:9C? *(check all that apply)*

☐ Class I-A ☒ Class II-A
☐ Class I-PL Pinelands Protection Area ☐ Class III-A
☐ Class I-PL Pinelands Preservation Area ☐ Class III-B

## SECTION E. RECEPTOR EVALUATION SUMMARY

**Non-UHOT Cases**

1. Have any of the following been identified on the site or within 200 feet of the site boundary?

   Check all that apply.

   ☒ Residences
   ☐ Child care facilities
   ☐ Public and private schools (K-12)
   ☐ Surface water
   ☒ Other occupied buildings
   ☒ Public parks and playgrounds

2. Did the well search conducted as a part of the receptor evaluation show any well use (potable, industrial, or irrigation)? ☐ Yes ☒ No

   If "Yes," indicate the type of use and approximate distance (closest occurrence) from site: *(Check all that apply)*

   ☐ Potable Distance from site: _____ feet

   ☐ Industrial Distance from site: _____ feet

   ☐ Irrigation Distance from site: _____ feet

3. Have any of these receptors been impacted? ☐ Yes ☒ No
   If "Yes," Do you have an NJDEP assigned Case Manager? ☐ Yes ☐ No

   If "Yes," please list the Case Manager: _____

**UHOT Cases**

1. Is ground water contamination above the Ground Water Remediation Standards? ☐ Yes ☐ No
   If "Yes," answer questions 2 and 3.
2. Has a potable well been identified within 100 feet of the contamination? ☐ Yes ☐ No
3. Have any potable wells been impacted? ☐ Yes ☐ No
   If "Yes," has the NJDEP been notified? ☐ Yes ☐ No

## SECTION F. PERSON RESPONSIBLE FOR CONDUCTING THE REMEDIATION INFORMATION AND CERTIFICATION

Full Legal Name of the Person Responsible for Conducting the Remediation: PPG Industries, Inc.

Representative First Name: Mark Representative Last Name: Terril

Title: Corporate Director Environmental Affairs

Telephone Number: (412) 434-2708 Ext.: _____ FAX: _____

Mailing Address: One PPG Place

City/Town: Pittsburgh State: PA Zip Code: 15222

Email Address: terril@ppg.com

This certification shall be signed by the person responsible for conducting the remediation who is submitting this notification in accordance with Administrative Requirements for the Remediation of Contaminated Sites rule at N.J.A.C. 7:26C-1.5(a).

*I certify under penalty of law that I have personally examined and am familiar with the information submitted herein, including all attached documents, and that based on my inquiry of those individuals immediately responsible for obtaining the information, to the best of my knowledge, I believe that the submitted information is true, accurate and complete. I am aware that there are significant civil penalties for knowingly submitting false, inaccurate or incomplete information and that I am committing a crime of the fourth degree if I make a written false statement which I do not believe to be true. I am also aware that if I knowingly direct or authorize the violation of any statute, I am personally liable for the penalties.*

Signature: Mark Terril Date: 2/28/2019

Name/Title: Mark Terril / Corporate Director Environmental Affairs

☐ Check this box if the person above is also the property owner of the site or their representative. If this person is not the site property owner, please ensure the site property owner's name and address is included in the DGW Proposal, and also indicate that the property owner has been informed about the proposed discharge.

**SECTION G. LICENSED SITE REMEDIATION PROFESSIONAL INFORMATION AND STATEMENT**

LSRP ID Number: _____

First Name: _____ Last Name: _____

Phone Numbers: _____ Ext.: _____ Fax: _____

Mailing Address: _____

Municipality: _____ State: _____ Zip Code: _____

Email Address: _____

This statement shall be signed by the LSRP who is submitting this notification in accordance with N.J.S.A. 58:10C-14, and N.J.S.A. 58:10B-1.3b(1) and (2).

*(1) I certify, as a Licensed Site Remediation Professional authorized pursuant to N.J.S.A. 58:10C-1 et seq. to conduct business in New Jersey, that for the remediation described in this submission, and all attachments included in this submission, I personally: Managed, supervised, or performed the remediation conducted at this site that is described in this submission, and all attachments included in this submission; and/or periodically reviewed and evaluated the work performed by other persons that forms the basis for the information in this submission; and/or completed the work of another site remediation professional, licensed or not, after having: (1) reviewed all available documentation on which I relied; (2) conducted a site visit and observed the then-current conditions and verified the status of as much of the work as was reasonably observable; and (3)concluded, in the exercise of my independent professional judgment, that there was sufficient information upon which to complete any additional phase of remediation and prepare workplans and reports related thereto.*

*(2) I certify:*

- *That I have read this submission and all attachments to this submission;*
- *That in performing the professional services as the licensed site remediation professional for the entire site or each area of concern, I adhered to the professional conduct standards and requirements governing licensed site remediation professionals provided in N.J.S.A. 58:10C-16;*
- *That the remediation conducted at the entire site or each area of concern, that is described in this submission and all attachments to this submission, was conducted pursuant to and in compliance with the remediation requirements in N.J.S.A. 58:10C-14.c;*
- *That the remediation described in this submission, and all attachments to this submission, was conducted pursuant to and in compliance with the regulations of the Site Remediation Professional Licensing Board at N.J.A.C. 7:26I; and*
- *That the information contained in this submission and all attachments to this submission is true, accurate, and complete.*

*(3) I certify, when this submission includes a response action outcome, that the entire site or each area of concern has been remediated in compliance with all applicable statutes, rules, and regulations and is protective of public health and safety and the environment.*

*(4) I certify that no other person is authorized or able to use any password, encryption method, or electronic signature that the Board or the Department have provided to me.*

*(5) I certify that I understand and acknowledge that:*

- *If I knowingly make a false statement, representation, or certification in any document or information I submit to the Department I may be subject to civil and administrative enforcement pursuant to N.J.S.A. 58:10C-17.a.1(a)through (f) by the Board, including but not limited to license suspension, revocation, or denial of renewal; and*
- *If I purposely, knowingly, or recklessly make a false statement, representation, or certification in any application, form, record, document or other information submitted to the Department or required to be maintained pursuant to the Site Remediation Reform Act, I shall be guilty, upon conviction, of a crime of the third degree and shall, notwithstanding the provisions of subsection b. of N.J.S.2C:43-3, be subject to a fine of not less than $5,000 nor more than $75,000 per day of violation, or by imprisonment, or both.*

*(6) I certify that I have read this certification prior to signing, certifying, and making this submission.*

LSRP Signature: _____ Date: _____

LSRP Name: _____

Company Name: _____

**SECTION G. SUBSURFACE EVALUATOR UST REPORT CERTIFICATION FORM**

*I certify under penalty of law that the work was performed under my oversight and I have reviewed the report and all attached documents, and the submitted information is true, accurate and complete in accordance with the requirements of N.J.A.C. 7:14B and N.J.A.C. 7:26E. I am aware that there are significant civil and criminal penalties for submitting false, inaccurate or incomplete information including fines and/or imprisonment.*

Name: _____ UST Cert. No.: _____

Firm: _____ Firm's UST Cert. Number: _____

Firm Address: _____

City/Town: _____ State: _____ Zip Code: _____

Phone Number: _____ Ext: _____ Fax: _____

# 1 INTRODUCTION AND IRM OVERVIEW

On behalf of PPG, Arcadis U.S., Inc. (Arcadis) prepared this Groundwater Interim Remedial Measure (IRM): Phase II Design and Permit-By-Rule (PBR) Authorization Request (Phase II Design) for the Garfield Avenue Group (GAG) sites, located in Jersey City, New Jersey (the site, **Figure 1**). The Phase II Design will be implemented at Site 114, which is located at 900 Garfield Avenue in Jersey City, New Jersey (**Figure 2**).

In order to expedite the treatment of groundwater associated with the portion of the GAG sites impacted with total and hexavalent chromium (Cr and Cr[VI], respectively), an IRM approach was developed consistent with the December 2016 technical memorandum titled, GW-050: Concepts for Groundwater Interim Remedial Measures for GAG sites, Jersey City, New Jersey (AECOM 2016) and subsequent discussions with the New Jersey Department of Environmental Protection (NJDEP) during May 2017. The IRM program was developed for phased implementation, with each phase representing a manageable portion of the affected area. The phased approach was intended to enable testing of the technical approach during the initial phase(s) and allow for continuous optimization of the process during successive phases. The IRM program is focused primarily on the intermediate and deep water-bearing zones that underlie areas where source removal has been completed and where elevated Cr(VI) is present in the groundwater.

The Phase I IRM is being performed in accordance with the Groundwater Interim Remedial Measure (IRM): Phase I Design and Permit-By-Rule (PBR) Authorization Request (Phase I Design; Arcadis 2017b) and included a combination of groundwater extraction within the northern portion of Site 114 for ex situ Cr removal and the reinjection of carbon-amended, treated groundwater in the southern portion of Site 114. Extraction operations within northern Site 114 served to recover groundwater containing the higher total Cr and Cr(VI) on site, while in situ anaerobic bioprecipitation (ISAB) was initiated in the southern section of Site 114 where Cr concentrations were lower and more amenable to bioremediation.

The proposed design for the Phase II IRM includes Cr treatment in both the northern and southeastern portions of Site 114 using a combination of groundwater extraction for ex situ Cr removal; and the reinjection of carbon-amended, treated groundwater or potable water for ISAB treatment. This Phase II IRM will be configured as follows:

- In the central portion of Site 114, groundwater will be recovered from areas containing elevated total Cr and Cr(VI) concentrations. This provides direct treatment of this area by removing Cr, resulting in less overall Cr in the subsurface. This area is also strategically advantageous to hydraulic operation, as the centralized site location enhances the subsurface progression of organic carbon and reactive zone distribution from both Phase II (north to south) and Phase I (south to north) IRM operations. Groundwater will be recovered for ex situ treatment and either reinjected or disposed to the sewer.
- In the northern portion of Site 114, a combination of localized groundwater extraction and substrate reinjection will provide a degradable source of organic carbon and foster development of a reactive zone for ISAB of Cr(VI) to trivalent Cr (Cr[III]) and subsequent precipitation and fixation of Cr within the aquifer matrix.

- In the southeastern corner of Site 114, groundwater will be recovered for ex situ treatment and permitted disposal to the sewer or reinjected with substrates to support ISAB in an area not included in the Phase I IRM.
- Similar to Phase I operations, the extraction/injection dynamics will help maintain the hydraulic balance inside the sheet pile enclosure around Site 114 and may also support flushing of Cr mass toward the extraction wells.
- Operation of the Phase I IRM remediation well network may continue intermittently in select areas in accordance with the existing Phase I IRM PBR (Arcadis 2017a) while Phase II operations are underway.

This design will advance ISAB treatment in the northern portion of Site 114 and facilitate ISAB treatment within the southern area of the site. During Phase I IRM operations, challenges pertaining to uniform reactive zone distribution within the heterogeneous Site 114 soils were encountered and have been considered in the Phase II design. To address this, supplemental injection techniques are currently being evaluated for subsurface permeability enhancement within the Phase I treatment area to improve treatment performance and the preferred methodology will be utilized in the Phase II program, as appropriate. The Phase II IRM program therefore leverages both design and operational insights gained during Phase I operations to enhance the ISAB process and allow continuous optimization of the treatment process.

## 1.1 Phase II IRM Objectives

Active treatment performed during the phased IRM program is being completed over a 3-year timeframe that includes approximately 1 year of active treatment per phase. Each active treatment phase is proposed to be followed by approximately 2 years of post-treatment monitoring. Phase I IRM extraction and injection operations were initiated during December 2017 and March 2018, respectively, and both were performed through 2018. Active Phase I treatment operations are anticipated to continue during the first half of 2019, following which post-treatment monitoring will be initiated.

Phase II IRM construction is expected to begin during the first half of 2019 with operational startup expected in mid-2019. The objectives of the Phase II program are to achieve the following:

- Establish anaerobic reactive zones to support ISAB reduction of Cr(VI) and total Cr within:
  - The northern portion of Site 114 where Phase I groundwater extraction was used to reduce Cr.
  - The southeastern portion of Site 114.
- Document post-treatment trends showing continuing attenuation/reduction of total Cr toward the Groundwater Quality Standards (GWQS).
- Capture site-specific information on the system operation to support subsequent IRM phases.

## 1.2 Regulatory and Permitting Considerations

Since Phase II of the IRM proposed injections to groundwater, a New Jersey Pollutant Discharge Elimination System (NJPDES) Discharge to Groundwater (DGW) PBR Authorization Request will be prepared and submitted. Pursuant to NJPDES rules (New Jersey Administrative Code [N.J.A.C.] 7:14A-

7.5 and 8.5) and Technical Requirements for Site Remediation (N.J.A.C. 7:26E-5.6), this report provides the PBR Authorization Request Form (**Appendix A**) and the detailed design describing the DGW activities.

In addition, because the DGW PBR involves operation beyond 180 days, a 30-day public notice is also required prior to the start of the groundwater discharge in accordance with 7:26E-5.6 (c)1-4. A draft public notice is provided as **Appendix A**. Proof of publication will be provided to NJDEP within 15 days after the notice is published.

Because the design also involves the withdrawal/removal of groundwater, either a Water Use Registration (WUR) or Water Allocation Permit (WAP) are required by the NJDEP Division of Water Supply (DWS). PPG currently maintains a WUR for the site (WUR100001) associated with the ongoing excavation dewatering efforts. The current WUR covers PPG Site 114 with an upper limit of total water from all diversion sources of 3.1 million gallons per month. The design for Phase II of the IRM relies on balancing the IRM-related groundwater extraction with the excavation dewatering extraction needs, such that the total dewatering will stay within the approved volumes of the current permit. The existing WUR permit (WUR100001) will be updated with the additional wells proposed for extraction purposes during the IRM, consistent with previous modifications.

This document provides the relevant technical background followed by the detailed design (and basis), operation, and monitoring plan for Phase II of the IRM.

# 2 TECHNICAL BACKGROUND

This section provides a brief summary of pertinent site background information, remediation history, site geology and hydrogeology, fate and transport of Cr in groundwater, and a discussion of Cr treatment technologies that have been evaluated for the site. A summary of relevant observations and design modifications gleaned from the Phase I IRM program are also presented for use in refining overall performance of the Phase II IRM approach.

## 2.1 Site Use, Remediation History, and Future Site Redevelopment Plans

In 1954, PPG acquired the 16.6-acre property from Natural Products Refining Company and processed chromite ore until 1963. In 1964, the plant was sold, and by 1976, chromite ore processing at the site had ceased. During the chromite ore processing operation, chromate chemical production waste (CCPW) was generated as a by-product from the production of sodium bichromate, including chromite ore processing residue (COPR), green-gray mud, and fill mixed with COPR or green-gray mud. Some of this material was used as fill around the site. These materials served as a source of Cr impacts observed in soil and groundwater at the site.

In 1990, PPG and NJDEP entered into an Administrative Consent Order (ACO) to investigate and remediate locations where CCPW or CCPW-impacted materials related to former PPG operations may be present. On June 26, 2009, NJDEP, PPG, and the City of Jersey City entered into a Partial Consent Judgment Concerning the PPG Sites, also referred to as the Judicial Consent Order (JCO), with the purpose of assessing the groundwater and sources of contamination at these sites as expeditiously as possible. The goal of the JCO was to complete the investigation and soil remediation activities at the PPG sites within 5 years. The selected approach for Cr-impacted soil is excavation and off-site disposal. Soil remediation at Site 114 was completed between July 2010 and January 2015. The final groundwater remedy is monitored natural attenuation (MNA), but this IRM is intended to advance groundwater treatment throughout all of Site 114 prior to the implementation of MNA.

The site is enclosed in steel sheet piling with internal shoring that bisects the site into east and west portions (**Figure 2**). The sheet pile is installed to variable depths along its length based on the site geology, with the majority of sheet pile section separating the western and eastern areas of Site 114 installed to approximately 55 feet below ground surface (bgs). Currently, the site is completely enclosed by a security fence with a main entrance gate at the intersection of Carteret Avenue and Halladay Street. A New Jersey Transit Rail Line bounds the site to the north, and a residential neighborhood is located to the west across Garfield Avenue. The southern and eastern boundary of the site is surrounded by light industrial and commercial areas near the New Jersey Turnpike Extension (Interstate 78). The eastern side of the site is the location of a former manufactured gas plant (MGP). Remediation of the MGP-impacted soils has been completed. The primary approach for soils impacted with MGP is excavation and off-site disposal.

The site is currently vacant, and remediation activities, including excavation of source mass, have been conducted. The City of Jersey City and the Jersey City Redevelopment Agency plan to redevelop the site

and a few surrounding sites into a multi-block retail and residential complex. The redevelopment will be implemented as a phased approach while the groundwater remediation is being conducted at the site.

## 2.2 Chromium Treatment Pilot Testing

In situ treatment of Cr(VI) is a well-developed technology (United States Environmental Protection Agency [USEPA] 2000), which may be implemented via chemical reduction and biologically mediated precipitation processes. Although chemical and biological treatment mechanisms differ, both treatment processes are designed to reductively precipitate and permanently fix/immobilize the Cr in the aquifer, reduce Cr concentrations in groundwater to enable achievement of treatment goals, and support long-term treatment permanence.

Pilot scale testing was completed to evaluate the feasibility of both ISAB and in situ chemical reduction (ISCR) technologies for treatment of Cr-impacted groundwater and saturated soil at the site per the Technical Execution Plan: Pilot Study for In Situ Treatment of Chromium Impacted Groundwater Using Reduced Iron/Free Sulfide Injections and Bioprecipitation (AECOM 2013). These tests provided information relative to the anticipated Cr treatment performance, reagent longevity and utilization, and yielded information pertaining to fluid injection and transport within shallow and intermediate water-bearing zone geologies. The primary findings from these tests were used to develop the IRM remedial program and are summarized below. Detailed descriptions of these tests were included in the Phase I Design, the Groundwater Bioprecipitation Pilot Test Completion Report (Arcadis 2017a), and in the Groundwater Chemical Reduction Pilot Study Completion Report (AECOM 2017).

### 2.2.1 Pilot Test Implications for IRM Design

The the Groundwater Bioprecipitation Pilot Test (Arcadis 2017a) and the Groundwater Chemical Reduction Pilot Study (AECOM 2017) were completed to evaluate the use of the ISAB and ISCR technologies as options to address elevated Cr(VI) concentrations present in the site's groundwater. Field-scale injection tests were used to assess the benefit of degradable organic carbon substrates (ISAB) and FerroBlack®-H and calcium polysulfide (CaSx) chemical reductants (ISCR) to demonstrate the effectiveness of the techniques. The results of performance monitoring of the ISAB and ISCR pilot tests suggest that complete treatment of Cr(VI) impacts were achieved in soil and groundwater at the site using both technologies. Specifically, the test results demonstrated the following:

- Both ISAB and ISCR technologies demonstrated the capability for rapid, effective, and permanent (at least 1-year post reagent injection) Cr treatment.
- Elevated organic carbon concentrations or chemical reductant and the related reducing conditions in groundwater persisted through the end of the performance monitoring period (12 months), which suggests treatment effectiveness may last for an extended period without additional reagent amendment.
- Injections were able to achieve distribution of reagent within the target footprint within the testing period. Where ISAB injection wells were used, average injection rates ranged between 0.5 and 1 gallon per minute (gpm).

- Injection limitations during the ISAB pilot test were observed related to the fermentation of organic carbon and the generation of gases within the subsurface, following sustained delivery of carbon substrate over extended timeframes. During the ISCR testing with Ferroblack©-H, the solid clogging of screens and surfacing under pressurized injection were observed related to the viscous nature of the blended FerroBlack©-H particulate and water mixture. These observations were considered in development of the IRM system design to accommodate adjustments of operating well locations, injection/extraction flow rates, substrate dosing cycling, and fouling mitigation techniques.
- Where groundwater pH was high, the ISAB pilot test was successful in moderating pH to a circumneutral range (approximately pH 7 standard units [S.U.]), which is advantageous for enhancing the long-term stability of precipitated Cr(III).

The evaluation of pilot test results (e.g., aquifer mobile fraction, injection flow rates and pressures, and reagent loading) also provided baseline design parameters for the Phase I IRM. Additional operational and performance monitoring insights during the Phase I IRM expanded on information obtained from the initial pilot tests, and this updated information has been used to make modifications to the Phase II IRM design.

### 2.2.2 Phase II Design Insights Derived from the Phase I IRM

The IRM program is adaptive, with operational and performance monitoring observations used to make routine modifications to each phase while underway and to support refinement of subsequent phase design. The Phase I IRM has been routinely adjusted over the course of operation, and observations of carbon substrate distribution and Cr treatment have provided a series of design element changes and operational adjustments that will be integrated into the Phase II IRM program.

The ISAB treatment approach implemented during the Phase I IRM has employed the routine delivery of molasses into the groundwater system to stimulate the native microorganisms and promote the development of an in situ reaction zone. Within the reactive zone, fermentation of the organic carbon substrate promotes development of iron- and sulfate-reducing groundwater conditions that are favorable for the reduction of Cr(VI). Under these conditions, Cr(VI) is reduced to Cr[III] through reactions with multiple biologically generated reductants or via direct anaerobic respiration with Cr(VI) serving as the terminal electron acceptor. Specifically, Cr(VI) is reduced to form less soluble Cr(III)-hydroxide via the following three major reduction mechanisms:

- Direct anaerobic respiration with Cr(VI) serving as the terminal electron acceptor (e.g., enzymatic extracellular reduction and intracellular reduction [Zhu et al. 2008]).
- Reduction by sulfide (hydrogen sulfide [$H_2S$], hydrosulfide [$HS^-$]) and ferrous iron (Fe[II]). Under reducing conditions, sulfide and Fe[II] will be produced from the reduction of naturally occurring sulfate and iron.
- Formation of an iron-Cr hydroxide complex that is less soluble and more stable than pure chromium hydroxide ($Cr[OH]_3$) (Sass and Rai 1987; Eary and Rai 1988).

The Cr(III) formed following Cr(VI) reduction is less soluble under site groundwater conditions and may be immobilized in the form of a hydroxide mineral that can be incorporated in a matrix of carbonate, sulfide, and other precipitates generated during the treatment process. The insoluble Cr(III) phases are also

resistant to re-oxidation to Cr(VI) phases under soil and groundwater conditions of the site. In addition to monitoring changes in both Cr(III) and Cr(VI) via the above mechanisms, performance monitoring data collected during the Phase I IRM were also used to evaluate the propagation of carbon substrate through the subsurface. These data were assessed using changes in total organic carbon (TOC) concentrations, which demonstrate the extent of the reactive zone and where conditions are most advantageous for Cr treatment. Other geochemical lines of evidence (e.g., iron, manganese, sulfate, methane) were also used to support this assessment, as the electron donor from the carbon substrate is also used to reduce naturally occurring metal species (iron and manganese) and support both sulfate reduction and methanogenesis. The carbon is expected to decline with increased distance away from the injection wells, so these supplemental geochemical indicators are useful in understanding where TOC may be depleted but where reactive species (e.g., iron sulfide) from the ISAB process may be observed and still contribute to Cr treatment within the ISAB anoxic fringe (Arcadis 2017).

Phase I IRM monitoring data meet the monitoring objectives in documenting development of both the reactive zone and anoxic fringe and have also been used to identify areas of Site 114 where geologic heterogeneities have limited carbon distribution and treatment performance. Where treatment was achieved, these observations were used to transition injection wells through the step-wise well network sequence identified in the Phase I Design (Arcadis 2017a). Where distribution was not observed or took longer than originally anticipated, injection wells were operated for longer durations to increase overall carbon delivery. These insights have provided valuable information to improve the design of the Phase II IRM program and account for geologic heterogeneities within the intermediate and deep water-bearing zones. System operational recommendations have also been identified based on Phase I performance. A summary of these is included below.

- **Organic carbon dosing** – Organic carbon pulsing during the Phase I IRM was performed between late March 2018 and December 2018 for daily periods approximately 4 to 6 hours in length. During each cycle, the molasses solution was mixed inline to achieve a dosing concentration between 0.5% and 3% (by volume) and distributed to the operating injection wells. After each carbon pulsing cycle, the injection of unamended, treated groundwater from the water treatment plant (WTP) or an on-site potable supply was used to continue injection until the subsequent carbon cycle. During the first 2 months of operation (March through May), a dosing strength between 0.5% and 1.0% was employed to evaluate the extent of potential biofouling within the conveyance network and limit potential fermentation gas buildup within the injection wells. When it was demonstrated that these could be successfully managed, the carbon dosing was increased further during late May to a 2% concentration that was generally maintained for carbon pulsing periods through December. Based on Phase I IRM operations, the Phase II IRM will be initiated using a 2% solution that will be delivered during 6-hour weekday pulsing cycles.
- **Injection well spacing** – Phase I IRM injection wells were installed on approximate, 75-foot on-center well spacing to support delivery of carbon substrate and unamended groundwater throughout the southern Site 114 reactive zone (**Figure 3**). This spacing was determined based on dose treatment response monitoring collected during the ISAB pilot test, aquifer testing performed previously at Site 114 and in advance of the Phase I IRM, and hydraulic simulations presented in the Phase I Design. Performance monitoring data demonstrated that propagation of the reactive zone within Site 114 occurred most readily within the intermediate water-bearing zone, where soils are generally more permeable, and that distribution within the lower permeability deep water-bearing

zone soils was less than anticipated. To account for the distribution limitations observed, most notably in the deep water-bearing zone, the 75-foot well spacing required operation of each of the Phase I injection steps for a longer period than originally anticipated to increase reactive zone expansion. To improve distribution during the Phase II IRM, the well network design has been modified to include a tighter, 50-foot on-center injection well spacing to increase the proximity of carbon injection locations and account for geologic heterogeneities that can otherwise reduce distribution.

- **Reinjection water sourcing** – Groundwater recovered from Site 114 and treated at the WTP served as the primary source of reinjection water over the course of the Phase I IRM, but potable water from an on-site source was also used during late 2018. Utilization of treated groundwater from the WTP is beneficial, as groundwater from the site can be returned to the aquifer at similar rates to that recovered via the extraction well network. Reinjection of treated groundwater is also advantageous, as it limits the amount of water recorded on a monthly basis under the existing WUR. Comparison of the two water sources, however, indicated that the use of the potable source resulted in less overall fouling of the injection conveyance network and allowed for higher injection flow rates at acceptable system injection pressures (less than 10 pounds per square inch [psi]). This is attributed to the consistent chlorine residual and lower concentration of inorganics (e.g., sulfate) present in the potable water supply that are useful in reducing biofouling. To capitalize on the benefits of both water sources, both sources will be used during the Phase II IRM. It is anticipated that treated groundwater will be used to offset the overall permitted discharge volume and that potable water will be used during warmer periods when biofouling contributes to increase system maintenance demands. Finally, operational monitoring data (e.g., flow rates, injection pressures) and unanticipated downtime at the WTP will also be considered in water source cycling.
- **Fouling mitigation steps** – The Phase I Design identified the advanced need to perform routine field fouling mitigation procedures to sustain injection flow rates and maximize injection well performance. It was anticipated, based on the previous operation of continuous-delivery carbon substrate injection systems, that subsurface fermentation gas generation and biofilm development within the injection wells would represent the most notable fouling challenge. These impacts were mitigated by the timing of pulsing cycles and routine introduction of unamended potable or groundwater that served to continually push carbon from the well screen into the surrounding formation. The most notable fouling during the Phase I IRM included biological growth that occurred within the conveyance piping and system components between the mobile injection unit (MIU) and the injection wells. This fouling was most notable during warmer periods when biological growth kinetics increased, and following periods of WTP disruption which contributed to redox changes in the MIU water source. Phase II Design recommendations include an increase in conveyance line clean-out locations and modification of valves and gauging components that have an increased tendency to foul.

In addition to the areas for Phase II Design performance improvement identified above, efficiencies related to day-to-day field operations will also streamline Phase II implementation and startup procedures. Details pertaining to how these recommendations are included in the Phase II Design are discussed further in Sections 3 and 4.

## 2.3 Site Geology and Hydrology

The site is located on the Jersey City peninsula, approximately midway between the Passaic River and the Hackensack River junction to the west (approximately 1.8 miles) and the upper bay/mouth of the Hudson River to the east (approximately 1.6 miles). Site observations from soil boring logs are consistent with the regional geologic mapping and generally include approximately 10 to 20 feet of poorly-sorted fill materials over organic-rich meadow mat. The meadow mat occurs throughout the majority of the site and marks the transition from the shallow fill aquifer (shallow water-bearing zone) to the underlying intermediate and deep water-bearing zones. Where the meadow mat is absent, the shallow water-bearing zone exhibits direct hydraulic communication with the intermediate water-bearing zone.

The hydrogeologic units present at the site have been historically classified as the shallow water-bearing zone (soils and groundwater above the meadow mat), the intermediate water-bearing zone (soils and groundwater below the meadow mat to approximate depths of 40 feet bgs), and the deep water-bearing zone (soil and groundwater between 40 feet bgs to bedrock). The transition zone between the intermediate and deep water-bearing zones is characterized by varved deposits consisting of alternating layers of silt, silty sand, and clay which separate the more permeable intermediate and deep water-bearing zone soils. The presence and thickness of these units depends on the relative depth to bedrock, which varies across Site 114. While not viewed as a separate hydrogeologic unit, the meadow mat that separates the shallow and intermediate water-bearing zones represents a semi-confining layer for the intermediate water-bearing zone (where present).

While characterized extensively via previous remedial investigation activities, additional insights into the high degree of heterogeneity of the intermediate and deep water-bearing zones were generated over the course of the Phase I IRM. Pre-design aquifer pump testing, well drilling observations, ongoing operational flow rates (injection and extraction), and supplemental vertical aquifer profiling (VAP) were all valuable in improving the understanding of soil type distribution and their bearing on permeability and reactive zone development.

### 2.3.1 Shallow Water-Bearing Zone

The shallow water-bearing zone includes unconsolidated soils and fill above the meadow mat and is present to approximately 20 feet bgs. The meadow mat is encountered at Site 114 at elevations of 0 to -5 feet (North American Vertical Datum of 1988). The shallow fill has been excavated to a large extent as part of the soil and groundwater remediation in the shallow water-bearing zone (completed at Site 114). A clean, uniform, dense-graded aggregate (DGA) was backfilled to grade and was, in some areas, complemented by a capillary break. In many areas of Site 114, the backfill was amended with FerroBlack®-H to prevent the clean fill from being re-contaminated with Cr-containing groundwater from the deeper water-bearing zones in areas where Cr remains elevated. The shallow aquifer depth to groundwater ranges from approximately 1 to 8.6 feet bgs and exhibits a downward vertical gradient when compared to the intermediate water-bearing zone. Horizontal groundwater flows is limited by the sheet pile walls, and the vertical flow is limited by the meadow mat.

The meadow mat consists of silt and clay with varying amounts of organic materials; however, in some areas, the organic deposits are thin or absent. The thickness of the meadow mat varies from less than 1

foot to approximately 6 feet and exhibits reduced hydraulic conductivity compared to the shallow fill and underlying intermediate aquifer.

### 2.3.2 Intermediate Water-Bearing Zone

The intermediate water-bearing zone includes unconsolidated soils below the meadow mat extending to the deep water-bearing zone, ranging in thickness from 5 to 20 ft, and is encountered across the GAG sites to a terminal depth elevation between approximately -50 and -60 feet. Within Site 114, intermediate soils are encountered at elevations between approximately 0 and -30 feet. The intermediate aquifer consists of fine-to-coarse sands or silty sand with varying amounts of silt and gravel. VAP sampling performed during previous investigation activities and the Phase I IRM indicates that the distribution of these more permeable intermediate zone soils is highly variable. At VAP borings within southern Site 114, loose, coarse sands and pebbles were encountered immediately below the meadow mat and were present in intervals of 1 to 5 feet in thickness. These materials grade to coarse or fine sands and contain increasing silt content with depth. The transition zone between the intermediate and deep water-bearing zones is generally characterized by the presence of increasing fines and the occurrence of varved deposits consisting of interbedded low permeability silt layers with silty sands or sandy silts. This transition zone can occur gradually or as sharp transitions within either the intermediate water-bearing zone (shallower than 40 ft bgs) or 10 to 20 feet deeper in the deep water-bearing zone. While these general trends were observed in VAP sampling, there is limited lateral continuity in the vertical profile of these interbedded varve sequences. This high degree of heterogeneity must be considered for design well spacing and injection volumes in order to propagate the subsurface reactive zone within the intermediate soils.

The hydraulic gradient in the intermediate aquifer is east to southeast or southeast and ranges from 0.002 feet per foot (ft/ft) to 0.004 ft/ft (March 2017 data). The estimated hydraulic conductivity in the intermediate water-bearing zone is up to approximately 5 feet per day (ft/day) and, assuming a porosity of 0.25, the estimated seepage velocity is approximately 0.04 to 0.08 ft/day. The flow is likely to be affected by leaking sheet pile and recharge associated with a nearby diabase contact parallel to Garfield Avenue.

The vertical hydraulic gradients are generally downward from the shallow aquifer and upward from the underlying, lower permeability, deeper aquifer. The vertical hydraulic gradient patterns are likely to reflect that the majority of advective groundwater flow and flux are occurring in the intermediate depth aquifer.

### 2.3.3 Deep Water-Bearing Zone

The deep water-bearing zone includes unconsolidated soils below the intermediate zone that extend to the top of bedrock. The thickness of the deep water-bearing zone varies based on the depth to bedrock, which deepens moving west to east across Site 114. The deep zone is encountered at Site 114 to terminal elevations of approximately -40 to -50 feet. The deep water-bearing zone consists of mixes of sand, silt, and clay with considerable variability in hydraulic conductivity and interbedding. The deep zone also includes low permeability till which is generally encountered below these sequences and overlies the bedrock. VAP characterization logs and soil borings indicate that the zones of highest relative permeability consist of silty sand or sandy silt and can be encountered with thicknesses of up to approximately 5 feet. These zones represent the primary intervals for groundwater and Cr transport within the deep water-bearing zone. Based on observations from the VAP logs and the Phase I extraction rates,

the bulk hydraulic conductivity for the deep water-bearing zone is generally an order of magnitude lower than observed in the intermediate depth aquifer. The higher degree and nonuniform distribution of low permeability soils within the deeper water-bearing zone has reduced hydraulic interconnectivity, which limited reagent delivery and reactive zone propagation within the Phase I IRM treatment area.

Depending on the location, the deep aquifer hydraulic gradient is east, east to southeast, and southeasterly and is approximately 0.005 ft/ft. Based on the VAP logs and assuming a porosity of 0.5, the seepage velocities in the deep aquifer range from less than 0.004 ft/day to approximately 0.04 ft/day.

### 2.3.4 Aquifer Testing Results

Pump testing activities performed in advance of Phase I IRM implementation were used to assess the range of anticipated sustainable flow rates and drawdown response expected following well installation. These data were also used to validate system sizing and hydraulic model assumptions. Initial testing was completed by AECOM in the northern area of Site 114, east of the pilot test area (AECOM 2015). Additional pre-design testing was performed by Arcadis during July 2017 prior to IRM implementation (Arcadis 2018).

Initial pump testing included a step drawdown pump test, a 3-day constant rate pump test, and a recovery test (to monitor the time taken for water levels to resume to the original conditions observed prior to pumping) between November 4 and November 17, 2014. These tests were conducted by extracting groundwater from the intermediate water-bearing zone well 114-MC-EW-103 (**Figure 2**). During the pumping test, a sustained groundwater pumping rate of approximately 3 gpm was achieved in 114-MC-EW103 over a period of 72 hours. Drawdowns at the monitoring wells were found to range between 25 feet (at the pumping well) to 4 feet (at an intermediate well located 27 feet away). No measurable water level drawdowns were observed at monitoring wells located more than 27 feet from the extraction well. Hydraulic conductivity estimates from both the pumping and recovery tests were found to range from 1 to 5 ft/day for the intermediate water-bearing zone. These estimates are consistent with representative values for silt sediments with varying amounts of fine sand, which were the main soil types observed across the well screens.

Between July 10 and July 27, 2017, four test wells (114-P1-IRM-9, 114-P1-IRM-23D, 114-P1-IRM-41I, and 114-P1-IRM-41D) were installed for pre-design testing. These wells were constructed in accordance with the PBR, which included installation of outer steel casings keyed into the meadow mat. Each of these well locations served as part of the IRM Phase I well network and were designed to accommodate both injection and extraction functions (**Figure 3**).

Hydraulic testing activities included initial step testing at 50% and 100% of the expected sustainable extraction rates, constant rate testing to achieve steady-state pumping at the selected pumping rates, stress testing to determine the maximum sustained pumping rate capable of dewatering the screen to 2 feet above the top of the well screen, and constant rate injection testing. Geochemical samples were also collected prior to hydraulic testing and during the test to assess changes in conditions due to pumping (Arcadis 2018).

As summarized in the Groundwater IRM Phase I Quarterly Report – Q1 2018 (Arcadis 2018), hydraulic conductivities ranged from 0.5 to 8 ft/day, with the lowest hydraulic conductivity observed in the deep aquifer well. This range was generally consistent with the 2014 testing and the parameters incorporated

into the IRM design. Sustainable extraction rates ranged from less than 0.5 gpm in the deep water-bearing zone to 3 gpm in the intermediate water-bearing zone. The achievable and sustained injection rates under moderate wellhead pressures (up to 5 psi) were generally consistent with the magnitude of the extraction rates. Analysis of the pumping test observation data supported the conceptual site model (CSM) of limited and negligible seepage from the shallow to the intermediate and deep water-bearing zones. These data indicate that, where the meadow mat is present, the intermediate/deep water-bearing zones are generally hydraulically disconnected from the shallow zone; however, seepage is known to exist in areas where the meadow mat is thin or absent.

### 2.3.5 Phase I Hydraulic Operations

Groundwater extraction operations during the Phase I IRM indicated that sustainable flow rates were within the range of previous hydraulic testing. In general, flow rates from extraction wells screened within the intermediate water-bearing zone were higher than that observed in the deep water-bearing zone due to the relative difference in permeability between units. Flows within the intermediate water-bearing zone generally ranged between 1 and 7 gpm, with flows in the deep water-bearing zone between 0.1 and 2 gpm. The one exception to this was well 114-IRM-40D, which exhibited sustained pumping rates between 5 and 7 gpm through much of the Phase I operational period. The decision to operate individual extraction wells at a given time during the Phase I program was made based on a balance between the following evaluation criteria:

- The well's spatial location near operating injection wells to enhance carbon distribution and reactive zone propagation within the extraction/injection well hydraulic dipole arrangement.
- The well's observed groundwater yield, with a focus on maximizing flow from the most productive locations.
- The magnitude of Cr observed in each extraction well, with a focus on maximizing groundwater recovery from wells containing the highest Cr concentration.
- A balanced distribution of operating extraction wells, with a desire to sustain flow from wells within the southwest and southeast carbon reinjection areas and the northwest and northeast Cr recovery areas.
- Any increase in organic carbon breakthrough associated with injection activities in the surrounding area that could exacerbate well or ex situ treatment system fouling.

Using the above evaluation criteria, the combinations of extraction wells used during Phase I sustained a total system extraction rate of 20 to 25 gpm for most of the Phase I period, which was in excess of the initial Phase I IRM design target of 17 gpm determined from the hydraulic model. Phase I observations indicate that extraction wells are likely to exhibit variability based on the stratigraphic features of the well location and, therefore, more Phase II remediation wells should be installed with extraction well capability to accommodate production rate variability in order to achieve the design flow rates.

Groundwater gauging activities were performed on at least a monthly basis between January and December 2018 in conjunction with the performance monitoring program to assess changes in drawdown and hydraulic gradients within the intermediate and deep water-bearing zones. Potentiometric maps for

these two zones are shown on **Figure 4**. Water levels were also collected from a series of shallow zone monitoring wells for use in assessing vertical gradients between all three units.

A review of Phase I potentiometric influence demonstrates the lateral and vertical hydraulic connection in the intermediate water-bearing zone. Relative areas of groundwater mounding are observed in the vicinity of the injection wells (**Figure 4**) when compared to observed cones of depression near extraction wells. The groundwater elevation patterns indicate that the injection/extraction network has been successful in establishing controlled and engineered groundwater flow patterns that focus groundwater flow toward the extraction wells. The presence of relatively high hydraulic conductivity aquifer materials in the intermediate water bearing zone have promoted successful distribution of carbon and injection and extraction of water volumes that met or exceeded the design criteria. The main challenge identified within the intermediate zone is likely the creation of localized hydraulic stagnation zones which can occur between operating injection wells or in locations where injection wells are operated adjacent to the sheet pile barrier. While enhancing the mounding associated with the injection program, the sheet pile barrier also limits flow and carbon distribution toward the barrier. Identification of these zones is important, as it informs how specific well locations can be addressed by sequentially cycling adjacent injection well operations over the course of several weeks or monthly time intervals.

Similar potentiometric patterns were observed in the deep water-bearing zone. The groundwater elevation contours demonstrate hydraulic control and engineered groundwater flow patterns from the injection wells toward the extraction points. The relatively lower permeability of the deep water-bearing zone has been apparent in the reduced injection and extraction volumes within this interval. Data collected over the course of Phase I also indicates that carbon distribution has not been effective in areas defined by less permeable soils. This difference in carbon distribution reflects the lower bulk hydraulic conductivity in the deep water-bearing zone and the discontinuous nature of zones of higher relative permeability. Carbon distribution has been achieved through the deep water-bearing zone soil intervals that are defined by higher advective flow but is less significant or not otherwise observed in zones that may be hydraulically isolated due to increased thicknesses of silt. As part of the Phase I IRM program, options for permeability enhancement and supplemental reagent delivery are currently being evaluated to better address lower permeability soils that also serve as Cr storage zones. For the Phase II IRM program, these observations serve as the primary rationale for increasing the overall density of the remediation well network by reducing the on-center well spacing. As applicable, permeability enhancement methods may also be incorporated in the Phase II IRM program as in Section 3 and is.

## 2.4 Nature and Extent of Chromium Impacts

### 2.4.1 Chromium in Groundwater

The primary site contaminant of concern (COC) in groundwater is Cr. Total Cr and Cr(VI) have been detected in the shallow, intermediate, and deep groundwater water-bearing zones of the site at concentrations exceeding the GWQS of 70 micrograms per liter (µg/L). Recent total Cr and Cr(VI) concentrations and iso-concentration contour maps for the intermediate and deep water-bearing zones are presented on **Figures 5** through **8**. As shown on these figures, both total Cr and Cr(VI) are primarily present in the intermediate and deep water-bearing zones with a reduced footprint and magnitude. As Cr, within the shallow water-bearing zone, has been excavated, concentrations above the GWQS were only

observed at a few localized areas at the site. Groundwater within the intermediate and deep water-bearing zones at Site 114 is confined by the existing sheet pile enclosures that reduce the likelihood of off-site Cr transport in groundwater. The historical total Cr and Cr(VI) data in groundwater are provided in **Appendix B**.

*Shallow Water-Bearing Zone*

The concentrations of Cr in the shallow water-bearing zone prior to the excavation work ranged from less than 1,000 µg/L to 16,000,000 µg/L. The concentrations of both total Cr and Cr(VI) and the areas with concentrations exceeding the GWQS of 70 µg/L for total Cr have been reduced as a result of the shallow water-bearing zone soil excavation and treatment of backfilled FerroBlack®-H material. Total Cr and Cr(VI) concentrations have been reduced below the 70 µg/L in most areas at Site 114, except for the pilot test area located in the northwestern portion of Site 114 and in a localized area surrounding monitoring well 114-P2B1-MW102S. Treatment performed under the Phase I PBR targeted the area in the vicinity of the former pilot tests and will continue in accordance with the Phase I injection and post-treatment monitoring program. Except for the pilot test area, areas within Site 114 that contain total Cr and Cr(VI) above the GWQS were backfilled with FerroBlack®-H material. Continued Cr treatment in the presence of FerroBlack®-H material in these areas is expected to continue over time.

*Intermediate Water-Bearing Zone*

Prior to implementation of Phase I, Cr concentrations at intermediate water-bearing zone monitoring wells, between 2015 and 2016, ranged from less than 1,000 µg/L to more than 1,000,000 µg/L with detected Cr and Cr(VI) concentrations observed up to 5,720,000 µg/L and 5,370,000 µg/L, respectively. The footprint of the Cr-impacted area has changed significantly under the influence of Phase I carbon injections in the southern area and groundwater extraction in the northern area of the site. The distribution of total Cr and Cr(VI) in the intermediate water-bearing zone based on data collected between October 30 and November 2, 2018 are shown on **Figures 5** and **6**, respectively. These data are also included in **Appendix B**.

As shown on **Figures 5** and **6**, Cr and Cr(VI) concentrations have been reduced to below 1,000 µg/L and to below detection, respectively, in the majority of the southeast and portions of the southwest corners of the Phase I treatment area. This area received carbon substrate delivery for the longest duration during Phase I operations. Cr is still observed within the northern half of the Phase I injection area where Phase I operations continued through the early December, approximately 5 weeks after the date of the sampling data. This area represents the primary area of treatment once Phase I operations resume during March 2019. Similar Cr reductions are expected in the northern half of the Phase I treatment area during continued operation of the Phase I well network during 2019.

Within the northern half of Site 114, changes have been observed in Cr due to ongoing operation of the groundwater extraction network. Concentrations have generally declined at most extraction wells operating during the Phase I program, which can be attributed to the ongoing Cr mass removal via extraction operations. As reported in the Groundwater IRM Phase I Quarterly Report for third quarter (Arcadis 2018b), over 17,000 pounds of total Cr and over 15,000 pounds of Cr(VI) had been recovered for ex situ treatment. Based on data collected through November, these mass removal numbers currently exceed 21,000 and 19,000 pounds for total Cr and Cr(VI), respectively. Collectively, the reduction in Cr

concentrations within the northern portion of Site 114 is consistent with the IRM objectives of reducing mass in this area prior to initiating the Phase II IRM ISAB injection program.

*Deep Water-Bearing Zone*

Similar to the intermediate water-zone, the implementation of Phase I injection and extraction operations have altered the Cr and Cr(VI) footprints in the deep water-bearing zone. The distribution of total Cr and Cr(VI) in the deep water-bearing zone are shown on **Figures 7** and **8**, respectively. The reductions in total Cr and Cr(VI) concentrations within the deep water-bearing zone are less extensive than that observed in the intermediate water-bearing zone. This is attributed to the more limited distribution of organic carbon substrate through the deeper, lower permeability soils. While some monitoring locations have shown limited change due reduced soil permeability, others have shown signs of improvement and highlight the degree of heterogeneity within the deeper water-bearing zone (e.g., 114-P1-IRM-10D). The deep water-bearing zone remains an area of focus as Phase I operations resume in 2019. Additional Phase I actions during 2019 will include ongoing organic carbon delivery in these areas where observed distribution has been more limited. As part of an amendment to the Phase I PBR, supplemental pilot testing is also being developed to evaluate an alternative injection method that can be used to enhance the relative permeability of more vertically extensive zones of low permeability soils that retain Cr. Improvements observed during these activities would also be used to adapt Phase II IRM activities, as warranted.

The highest concentrations of total Cr and Cr(VI) within the Phase I IRM monitoring network exceed 1,000,000 µg/L at well 114-P1-MW7D, within northern Site 114. Similar to the intermediate zone, reductions in Cr have been observed at operating deep extraction wells, consistent with the IRM objective related to achieving overall mass removal.

### 2.4.2 Chromium in the Soil

Cr impacts in shallow water-bearing zone soils have been removed via excavation, and soil concentrations in exceedance of the Non-Residential Direct Contact Soil Cleanup Criteria (NRDCSCC) have been identified within the intermediate and deep water-bearing zones. These exceedances are attributed to the high dissolved-phase concentrations that result in an elevated saturated soil sample response. As soil Cr impacts in the intermediate and deep water-bearing zones are a reflection of the dissolved-phase concentration, soil impacts are expected to decline via the IRM groundwater treatment program. The historical total Cr and Cr(VI) data in soil are provided in **Appendix B** of the Phase I IRM Design (Arcadis 2017b).

### 2.4.3 Other Contaminants

Additional contaminants historically detected above the applicable GWQS values at Site 114 include Target Analyte List (TAL) metals, cyanide, petroleum hydrocarbon compounds, volatile organic compounds (VOCs), and semi-volatile organic compounds (SVOCs) associated with former MGP operations. While metals have been detected across Site 114, VOCs and SVOCs were primarily observed at localized areas in the eastern portion of the site (e.g., 114-MW20B). Based on the most recent sampling events (September 1, 2015 through June 1, 2018), the following COCs were detected above the applicable GWQS values:

- **Metals** – antimony, arsenic, beryllium, cadmium, cobalt, lead, nickel, silver, strontium, thallium, and vanadium
- **VOCs** – benzene, ethylbenzene, toluene, xylenes, tetrachloroethene, trichloroethene, cis-1,2-dichloroethene, vinyl chloride, chlorobenzene, 1,1-dichloroethene, 1,2-dichloroethane, 1,2,4-trimethylbenzene, 1,2-dichlorobenzene, 1,4-dichlorobenzene, 1,2,4-trichlorobenzene, and styrene
- **SVOCs** – benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, 1-methylnaphthalene, 2-methylnaphthalene, bis(2-ethylhexyl)phthalate, pentachlorophenol, 1,4-dioxane, naphthalene, hexachlorobenzene, benzo(k)fluoranthene, and indeno(1,2,3-cd)pyrene

While the concentrations of these COCs were lower compared to Cr and are not the primary targets of the IRM program, these additional COCs have been considered as part of the IRM program development and will be addressed via IRM treatment operations. Similar to Phase I operations, these contaminants are expected to be treated with the existing WTP (e.g., via metal precipitation, granular activated carbon [GAC] adsorption, and filtration) or may be otherwise utilized as supplemental organic carbon substrates for ISAB or degraded via natural biological degradation (e.g., VOCs and SVOCs).

As detailed in Section 3.1.3, operation of the water treatment system has been effective in reducing these concentrations prior to discharge. Ongoing monitoring of these COCs will continue to demonstrate that sufficient treatment (i.e., a 95% reduction between influent and effluent concentrations or removal to below the applicable GWQS, whichever is smaller), is achieved for reinjection use over the course of the IRM.

# 3 PHASE II IRM DESIGN: INTERMEDIATE AND DEEP WATER-BEARING ZONES

Activities proposed as part of the IRM Phase II and summarized in this PBR request include the following:

- Implementation of ISAB to initiate and sustain biological treatment in the northern and southeastern areas of Site 114 while leveraging groundwater extraction within the northern, central, and southeastern portions of Site 114 to remove Cr mass.
- Extraction and reinjection activities included as part of the Phase II IRM are designed to address intermediate and deep groundwater horizons, utilizing both biological degradation and physical extraction means.

Each of these PBR elements are presented in the sections below.

## 3.1 IRM Design Basis and Infrastructure

The ISAB treatment program builds on successful results achieved during pilot testing and Phase I activities. The IRM Phase II program will rely on an injectable organic carbon substrate (e.g., molasses, emulsified vegetable oil [EVO]) to establish reduced geochemical conditions and to stimulate the native microbial community to support reduction of Cr(VI) to Cr(III). As detailed in Section 2.2, this process is facilitated by several primary mechanisms that foster the precipitation and fixation of Cr(III) in aquifer soils. To achieve ISAB treatment within the northern and southeastern areas of Site 114, the IRM program has been developed with a well network designed to allow sustained delivery of potable or treated groundwater that has been amended with organic carbon into the subsurface. Groundwater extraction activities concurrent with ISAB reinjection will serve the following primary objectives:

- Provide a source of water for sustained ISAB injections.
- Maintain hydraulic conditions within the Site 114 sheet pile to limit mounding during sustained injection activities.
- Support removal of Cr(VI) concentrations from the northern portion of Site 114.

As demonstrated during the pilot test and the Phase I IRM, the propagation of both organic carbon and reduced groundwater chemical species (e.g., Fe[II], sulfide) through the subsurface collectively support Cr(VI) to Cr(III) reduction and precipitation (Arcadis 2017; Arcadis 2018). To accomplish this for Phase II, the proposed well network will be used adaptively over the course of operation in conjunction with systematic modification of extraction and reinjection flow rates, well configuration (i.e., extraction or injection), and organic carbon dosing. The recommended well network was developed based on incorporating existing site information and observed Phase I data into a groundwater and solute transport model (Section 3.1.1). This model was used to determine specifications for well spacing, vertical installation, and operational sequencing based on previously identified hydraulic information and observations from Phase I operations. While the model serves as a basis for conceptual design, Phase I challenges related to Site 114 soil heterogeneity and the presence of low permeability strata in the deep water-bearing zone must be considered as part of Phase II implementation. High-resolution lithologic profiling and VAP sampling performed as part of the Phase II well installation will be used to better refine

the understanding of relative permeability and Cr distribution across the intermediate and deep water-bearing zones, will allow targeted placement of injection and extraction well screened intervals, and will be used to identify zones for potential permeability enhancement via fracture-based injection techniques. The following sections present the modeling and design basis and the Phase II well network, water treatment, and conveyance infrastructure specifications.

### 3.1.1 Recirculation Flow and Solute Transport Modeling

Historical geologic and hydraulic information, together with the observations from Phase I implementation, were utilized to optimize the design well network within the Phase II IRM treatment areas. The groundwater flow and solute transport model constructed for Site 114 in the Phase I Design was also updated to improve predictability of the model based on Phase I information. These changes are detailed in **Appendix C** and were used to optimize the spacing, orientation, and operational sequencing of the Phase II well network. This modeling approach helps ensure the extraction and injection activities at Site 114 avoid hydraulic mounding within the sheet pile walls and can reasonably estimate organic carbon distribution during the Phase II operational timeframe. The model also serves as a tool to revisit potential optimization activities during the Phase II operation.

As detailed in **Appendix C**, MODFLOW was selected for the construction of the numerical groundwater flow model. The model extents are limited to the Site 114 boundary that follows the perimeter sheet pile walls as an effective hydraulic control for the majority of the site. The model is composed of four vertical layers that discretely represent the shallow fill, meadow mat, intermediate, and deep aquifers. The base of the model represents the contact between the bottom of the deep aquifer and the underlying till and/or bedrock. Hydraulic parameters, such as hydraulic conductivity and recharge, were assigned within ranges of observed values based on site slug tests, aquifer tests, and literature values. Iterative remedy simulations were then conducted to evaluate the temporal change in heads during remedy operations. Once the groundwater flow model was constructed, solute transport modeling was performed using Modular 3-D Transport Model (MT3D) and MT3D Multi-Species (MT3DMS). The solute transport modeling was used to represent the development of the ISAB reactive zone based on carbon substrate injection simulations during the first 6 months of Phase II operations.

Prior to simulating proposed Phase II operations, the groundwater flow and solute transport model was run using the actual Phase I operational data in order to compare water levels and the observed development of the ISAB reactive zones to the previously simulated Phase I carbon substrate injection results. Simulated and observed water levels indicate a reasonable fit and support the existing flow model parameters. The solute transport model also indicated a good correlation between the simulated and observed reducing zones for the intermediate water-bearing zone, while the simulated results for the deep water-bearing zone indicated development of a much larger reactive zone than what was observed during Phase I. To improve the match of the simulated transport results in the deep water-bearing zone (model layer 4), the mobile and immobile porosity values were incrementally adjusted from 10% and 25%, respectively, to 15% and 20%. This preserved the total porosity at 35% but allowed for a slower development of the reactive zones in the deep interval that was more consistent with what was observed. These adjusted solute transport model parameters coupled with the limited injection rates in the deep unit observed during Phase I operations were used to refine and tighten the spacing in the Phase II well network to maximize substrate distribution and reactive zone development in the target areas.

The groundwater flow and solute transport model were used to identify an initial IRM design consisting of 144 new injection wells and 20 new extraction well positions. The 144 injection wells were split between 103 injection locations in the northern area and 41 wells in the southeastern area. These wells include both intermediate and deep injection intervals to span the potential 20- to 40-foot Cr-impacted thickness within model Layers 3 and 4. The well network includes variable sequencing that utilizes wells operated for injection purposes and wells that are shifted from extraction to injection purposes to control hydraulic mounding during different steps of the Phase II program. Dedicated Phase II extraction wells are located in the central area of Site 114 and are located in areas that are hydraulically advantageous to maximize mass removal and support Phase II reactive zone propagation from north to south and to further enhance reactive zone development in the Phase I area from south to north.

Iterations of the site-specific injection and extraction flow rates and the Phase II well network indicated that a combined total injection and extraction rate of 21 gpm and 12 gpm within the northern and southeastern Phase II areas, respectively, can achieve organic carbon distribution during the operational period based on model parameters. While the model indicates reactive zone coverage can be achieved over a 6-month duration where aquifer properties are like those in the model, Phase I operation has demonstrated that distribution behavior will vary based on unique geologic heterogeneities in different areas of the site. Therefore, where achievable, injection and extraction rates will be increased to maximize the total quantity of groundwater extracted and injected within the capabilities of both treatment areas (40 gpm each) and within permit specifications. Over the course of operation, the Phase II design entails initiation of injection activities within the northern end of Site 114, followed by gradual southward shifts in operating wells. Based on the model flow rates, these have been conceptualized as three, 8-week cycles (**Appendix C**). Similarly, injection activities in the southeastern area will gradually shift further east during the Phase II operation. While the model assumptions are helpful in predicting the progression through the individual steps during the operational period, individual cycles may be extended in length (e.g., to 12 or 16 weeks) based on performance and observed reactive zone development.

As observed during Phase I IRM operations, geologic heterogeneities within the intermediate and deep water-bearing zones influenced reagent and reactive zone propagation within the recirculation area. This resulted in extension of the anticipated timeframes for each operational step based on performance monitoring observations. A similar approach will be adopted for Phase II, with the predicted sequencing timeframes above adapted, as necessary, based on operational and performance monitoring results. The reduction in on-center injection well spacing from 75 feet (Phase I) to 50 feet (Phase II) will also shorten the necessary reactive zone propagation distance between well locations and will serve to help overcome natural geologic controls that might otherwise limit distribution and treatment extent. While the model developed for Phase II operations serves to support well spacing configuration and duration estimates, it will also be leveraged over the course of the remedy to review and refine remedial operations based on additional geologic information obtained during well installation, hydraulic operational observations, and water quality monitoring. This information will enable use of the model as a predictive tool or to evaluate remedy performance, while monitoring information will be used to assess overall treatment progress and adapt remedial operations.

### 3.1.2 Extraction and Injection Well Design

The 144 new injection wells and 20 new groundwater extraction wells identified based on the observed Site 114 Cr distribution and hydraulic modeling outputs include discrete screened intervals to provide injection access to both the intermediate and deep water-bearing zones. The Phase II well installation program is anticipated to include a combination of hydraulic profiling tool (HPT) and vertical aquifer profiling (VAP) sampling methods to refine the understanding of Cr and lithologic vertical distribution to support final determination of the injection, extraction and monitoring well network. While HPT and VAP sampling will not be applied at all well locations, it is anticipated that the initial subset of wells (and up to 25% of the overall network) will utilize a combination of these sampling methods. Following these activities, drilling observations during installation and baseline groundwater sampling from each location will be used to further refine the understanding of geologic profiles and Cr distribution to optimize overall well placement. Collectively, this information is intended to support placement of injection and extraction well screens to address the vertical profile of the intermediate and deep water-bearing zones that contains Cr. Similar to the Phase I IRM well installation, injection/extraction wells are expected to entail longer well screens up to 20 feet in length to overwhelm potential heterogeneities within the intermediate and deep soils and allow propagation of the reactive through the soils of higher relative permeability.

Insights from all well installation activities will also be used to guide any modification in well network sequencing or recirculation flow balancing to achieve the IRM objectives. Examples of this include identification of areas with higher Cr concentrations and greater permeability that will represent an area for increased treatment focus or reduction in flows at wells installed in areas that do not require treatment. The layout and vertical interval specifications for IRM Phase II extraction and injection wells identified via the model are considered to be a conceptual representation of the final network, understanding that further refinements may be made in response to geologic and baseline analytical data consistent with the adaptive remedial program. For PBR approval purposes, it is assumed that up to 160 total injection wells and 30 total extraction wells will be installed. The proposed IRM Phase II remedial well layout is shown on **Figure 9**, and the remediation well construction details are included in **Table 1**.

The conceptual designs of the extraction and injection well completions are summarized on **Figure 10** and are consistent with the well construction used in the Phase I IRM. All remediation and monitoring wells will be installed by a union, New Jersey-licensed well driller and completed in accordance with the N.J.A.C. 7:9D. Drilling will use a step-wise process that entails hollow stem auger (HSA) to advance an outer, shallow protective casing with the meadow mat; this will then be followed by mud rotary drilling to achieve the target depths for well installation. As applicable, a Geoprobe rig may also be used to confirm the depth of the meadow mat prior to advancing HSA. The drilling approach and well designs include the following:

- Drilling with a 6.25-inch inner diameter HSA or similar drilling technologies to the meadow mat for installation of an outer steel casing to establish a grouted, competent seal and eliminate hydraulic communication between the shallow and intermediate aquifers.
- Following adequate curing time and using mud rotary drilling techniques advanced through the shallow protective casing, installation of 4-inch stainless steel screens (10-slot with #0 sand pack) for remediation wells and 2-inch Schedule 40 polyvinyl chloride (PVC) for monitoring wells at the specified depth intervals.

- Installation of Schedule 40 PVC riser to approximately 3 feet above ground or completed with flush mount well vaults.
- The wells will be finished with stick up mounts or completed with flush mount well vaults. Locking covers will be placed over each wellhead assembly.

During well completion, hydrated bentonite and grout will be used to seal the annulus to the surface. While flush mount well completions are currently considered a part of the design, the option of using stick-up well construction will be reviewed during the final wellhead and system conveyance infrastructure design. Final well completion determination will also account for surface elevation changes that occur as a result from regrading activities performed during site restoration activities. As applicable, protective bollards may also be installed to prevent well damage during the IRM.

For the purposes of this PBR, individual well screen lengths are proposed to range between 5 to 20 feet in length, which will be further refined based on high-resolution sampling results obtained during the drilling program, the soil stratigraphy observed during drilling activities, the distribution of Cr, and the updated CSM. At the outset of Phase II drilling activities, a combination of high-resolution lithologic profiling using a HPT and VAP sample collection will be used to map the soil and Cr distribution within the intermediate and deep water-bearing zones. These methods will be used for all proposed monitoring well locations and at subset (approximately 20) of the remediation wells. Data collected during these activities will be used to determine the preferred interval for monitoring well screen placement and to expand the understanding of soil heterogeneities within the Phase II treatment area. High resolution data will then be used to support finalization of the target screen intervals for the rest of the Phase II IRM well network.

Within the extraction wells, well pumps will initially be set at the midpoint of the screened interval, and drawdown will be adjusted using control valves based on readings from a pressure transducer installed in the well. This is intended to limit over pumping the extraction wells, to limit exposing the screen to air (and oxygen), and to control well fouling. The location of the extraction well pump within the screen interval may be adjusted based on field and system performance observations. Based on previous hydraulic testing and Phase I observations, it is assumed that average extraction rates per well may be up to 3 gpm. Where feasible, extraction rates will be increased based on the specific capacity of the aquifer at a given well location.

Initially, the injection wells will be equipped with a drop tube to approximately 2 feet below the seasonal low groundwater elevation to convey the injected recirculation water and carbon amendment to the saturated interval and thereby limit aeration of the injection water and bubble entrainment within the reinjection stream. Based on field and system performance observations, the depth of the drop tube may be adjusted by using an inflatable packer to focus the injection flow to specific treatment zones. Each active injection well will be equipped with a pressure transducer installed in the well to monitor the water level of the well. Based on previous testing at the site and the common ratios of injection well capacity relative to injection wells, it is estimated that injection rates may vary between 0.5 to 3 gpm per well. Similar to extraction operations, injection wells may be operated at higher flow rates, depending on the nature of the soil formation and ability to receive fluids.

### 3.1.3 Ex Situ Groundwater Treatment

The ex situ treatment system will be used to handle extracted groundwater for treatment, carbon substrate amendment, and injection to support the IRM ISAB recirculation approach. WTP operation will be conducted in accordance with the existing WUR for the site (WUR100001), with the treatment train qualified to address an anticipated extraction and injection flow rate of up to 60 gpm. Each of the recirculation systems will be capable of handling 40 gpm, but it is not expected that both will operate at these flows for the duration of the Phase II program. For PBR purposes, it is assumed that Phase II operations will entail up to 60 gpm of total system flow over 12 months of operation, resulting in a total recirculated volume of 31.5 million gallons. This equates to approximately 2.63 million gallons per month, which is within the WUR permit specifications and still leaves capacity for excavation dewatering needs, as necessary.

As detailed in Sections 2.4.1 and 2.4.3, the primary COC is Cr(VI), with concentrations up to or above 1,000,000 µg/L. Low levels of other metals, VOCs, and SVOCs are also encountered within Site 114. The current water treatment system has been used effectively to achieve removal of these target COCs and comply with permit requirements during previous excavation dewatering activities.

Over the course of operation, the water treatment system will be monitored for flow rate and treatment management. The conservative 60 gpm flow rate proposed for the IRM still allows enough system capacity within the WUR for anticipated excavation dewatering needs. There may be transient occurrences where excavation dewatering needs to be increased to accommodate recharge from significant storm events, and total IRM flow rates during these potential durations can be temporarily reduced to remain within the WUR. Treatment system management includes ongoing review of influent and effluent COC concentrations at the water treatment plant to ensure that reinjected water meets the requirements of the PBR. The treatment of COCs in the effluent groundwater used for reinjection will be sufficient to achieve either 95% reduction of influent levels or below the applicable GWQS values, whichever is less stringent. Based on the groundwater sourced to the treatment system, a review of individual COCs will be performed to ensure that these treatment objectives are met. The water treatment train will consist of the following basic unit process elements:

- Groundwater extraction
- Equalization
- Chemical reduction (Cr[VI] reduction)
- Chemical amendment (coagulation and flocculation)
- Phase separation (solids removal)
- Filtration
- Adsorption (VOC removal and Cr[VI]/metals polishing)
- Chemical amendment (organic carbon amendment) for the treated water that will be injected into the subsurface
- Solids management (e.g., solids thickening, dewatering, and disposal)

The treatment system will facilitate continuous operation while minimizing operator input and manual system operations to the extent practical. Similar to previous site operations, dewatered treatment residuals will be stored on site prior to off-site disposal.

### 3.1.4 Recirculation Conveyance and Reagent Mixing

The conveyance infrastructure for the Phase II system will be designed to facilitate adaptive extraction and injection operations. The design will allow flexibility for reuse of conveyance materials with different well sequencing and to accommodate changes related to other site activities (e.g., earthwork and dewatering operations). A conceptual layout of the conveyance infrastructure is presented on **Figure 11**.

The water conveyance piping for the extraction wells will be standard dimension ratio (SDR) 11, high density polyethylene (HDPE) double-contained piping. The 2-inch carrier pipe and 4-inch containment pipe will readily accommodate the anticipated flow rates of 1 to 3 gpm per well. The double containment will protect against leaks and prevent damage to the piping. A pumping station will be constructed to collect groundwater pumped during Phase II extraction and transfer the water to the existing water treatment system. Individual laterals from each well will discharge directly into the pump station without connecting to a header pipe. Double-contained discharge piping from the pump station will be connected into the existing 2-inch by 4-inch double-contained HDPE piping, which runs from Site 114 to the existing groundwater treatment system.

In addition to the extraction conveyance piping, 2-inch, non-metallic electrical conduits will be installed between each extraction well and the water treatment system. Each extraction well will have two conduits, one for pump power wiring and the other for instrument signal wiring. The conduits will be installed alongside the conveyance piping to each well with adequate separation between the power and signal wire conduits to prevent interference. The conveyance piping and conduit for the extraction wells will be installed within a trench and protected with a soil cover of at least 3 feet deep, which both protects these utilities from damage and the elements and prevents water from freezing within the pipes. Buried utility runs will be marked with colored stakes at regular intervals as visual indicators.

Treated groundwater for reinjection will be routed to two injection systems staged in the southern part of Site 114. These systems will contain a storage tank for the stock reagent solution and appropriate metering pumps, in-line mixing components, and manifolds to control carbon substrate amendment into the treated groundwater prior to delivery into operating injection wells. Dynamic operation of these systems will also be used to toggle between periods of carbon substrate pulsing and treated groundwater reinjection alone. One trailer-mounted system was installed for Phase I injection activities and will be reused for Phase II. A second system, installed in a shipping container, will be fabricated off site and delivered to the site for installation and use for Phase II. System design will also include storage and dosing equipment to meter a glutaraldehyde-based biocide solution in to the injection system piping to prevent fouling of the wells or piping due to growth of biomass. A Safety Data Sheet (SDS) for the proposed chemical is included in the **Appendix D**.

The treated water conveyance piping between the water treatment system and each injection system will be a 2-inch SDR11 HDPE single-walled pipe that will carry the anticipated 40 gpm maximum design flow for injection at each well field. New conveyance pipes will be connected to the existing piping, which was installed and used for Phase I operations. Separate 2-inch pipes will be installed to each of the Phase II injection system locations. Two-inch non-metallic electrical conduits will be installed between the new

injection trailer and the water treatment system. Existing electrical conduit will continue to be used for the existing injection trailer. Each trailer will have two conduits – one for power wiring and the other for instrument signal wiring. The conduits will be installed alongside the conveyance piping to each trailer with adequate separation between the power and signal wire conduits to prevent interference. Similar to the extraction well utilities, the injection trailer utilities will be buried and marked. The injection trailers will be strategically located at both injection well fields to minimize the need for trailer relocation.

Each injection system enclosure will be outfitted with an injection manifold and instrumentation to monitor and inject treated and amended water to all active injection wells during each step of Phase II. Instrumentation will be installed at the injection manifolds to allow for pressure and flow monitoring for the active injection wells. Heat tracing and pipe insulation will be used to prevent any exposed pipes from freezing. Injection water will be conveyed to the active injection wells from the injection manifolds through ½ inch Schedule 80 PVC piping. Individual pipes will be installed from injection wells to the corresponding injection system enclosure. Injection pipes will be buried in a similar fashion to the extraction well piping, and the pipe locations will be marked using colored stakes at regular intervals as visual indicators.

If there is a need to move or alter the utilities to accommodate adaptive system operation, such as repurposing wells, or to accommodate other site activities, hoses, piping, and conduits can be uncovered and relocated or altered, as necessary. The use of flexible hoses, HDPE piping, and non-metallic conduit allows for flexibility in the utility layouts. Alternative methods of covering and protecting the lines will be considered during development of the final conveyance infrastructure design and may include burying portions of the delivery lines or using heat trace to eliminate freezing risk. During periods where freezing conditions are not a concern, piping may temporarily be installed on the ground surface if short-term injection of amended groundwater is needed at individual wells.

## 3.2 IRM Operation: Intermediate and Deep Water-Bearing Zones

### 3.2.1 Adaptive Management Overview

An integral component to successful groundwater recirculation remedies is maintaining an overall degree of adaptability over the course of operation to respond to field observations and to maintain the pace of overall remedial performance. Key aspects of the performance include Cr concentration reduction, mass recovery (from extraction wells), organic carbon distribution, and evidence of reduced groundwater geochemical propagation within the subsurface. These indicators will be assessed as part of the Groundwater Monitoring Program (Section 4) and used to adapt overall extraction and injection operations during Phase II.

The conceptual layout for the IRM Phase II well network is provided on **Figure 9** and in **Appendix C**, which includes variable groups of injection wells that will be sequenced (turned on and off) strategically over the course of the Phase II program to deliver both organic carbon and treated groundwater uniformly through the subsurface. Performance data will be used to guide system operation and adjust well sequencing to meet the overall Phase II objectives. Data that will be evaluated continuously to optimize the remedial performance include, but are not limited to, the following:

- Monitoring well water quality data, including laboratory data (e.g., TOC, total Cr, and Cr[VI]) and field parameters (e.g., dissolved oxygen [DO] and oxidation-reduction potential [ORP])

- Extraction well water quality data (e.g., TOC, total Cr, and Cr[VI])
- Individual extraction and injection well flow rates
- Treatment system influent water quality
- Changes in the overall Cr distribution extent and plume footprint

The pulsing of carbon amendment in concert with the sequenced extraction scheme is key to overcoming aquifer heterogeneities, ambient hydraulic gradients, and preferred flow paths. Injection sequencing in the northern area of Site 114 will be implemented stepwise from north to south and in the southeastern corner of Site 114 from the west to east. Select extraction wells will be used during steps 1 and 2 in the northern area, and continuous extraction from the central portion of the site are intended to provide mass removal, support southward carbon delivery, and balance the water demand required for injections. The specific timing of transitions between injection wells will be assessed based on the observations listed above. As the IRM Phase II progresses, specific adjustments (e.g., wells for extraction and injection, flow rates, organic carbon dosing) will be made to optimize the system's performance. These adjustments will likewise be based on the observations listed above and include the following:

- Increases and decreases in individual extraction well pumping rates to optimize mass recovery, distribute organic carbon, and promote hydraulic control.
- Adjustments of individual injection well flow rates and duration of carbon amendment pulsing. This includes substrate dosing and volume adjustments to refine hydraulic control and optimize the distribution of organic carbon.
- Strategic conversion of extraction wells to injection wells or injection wells to extraction wells to optimize mass recovery, organic carbon distribution, and hydraulic control. This may also include the installation of additional extraction and/or injection wells.
- The use of treated groundwater or a potable water supply for reinjection and recirculation purposes.
- Strategic adjustments to the extraction scheme to ensure water chemistry and flow rate meets the treatment systems operational requirements.
- The type of organic carbon substrate (e.g., molasses and EVO) used and the relative dosing strength to induce and sustain the bioprecipitation processes in situ.
- The timing of organic carbon substrate dosing and recirculation shutdown and initiation of rebound monitoring.

The above management framework is advantageous in that it enables routine optimization for maximum Phase II efficiency. Each of these steps also serve to develop insights into supporting the transition of Phase II operations into subsequent phases of treatment at the GAG sites.

As reduction in Cr concentrations are achieved within the IRM Phase II area and attention turns to subsequent IRM treatment phases, select Phase II wells may continue to be operated as injection or extraction wells to maintain treatment performance during the transition. This will support hydraulic control, organic carbon distribution, and mass removal.

In addition to the adaptive modifications specified above and as identified in the preceding sections, alternative injection strategies are currently being considered to enhance or augment the Phase II treatment operations. Pilot testing completed previously at Site 114 included other methods of injection delivery, such as Direct Push Technology and hydraulic fracturing methodologies, to emplace solid-phase reagent material (e.g., Ferroblack®-H). Similar methods are currently being considered for subsurface permeability enhancement in the Phase I treatment area and will also be used during the Phase II program for lithologic zones that contain Cr and are not receptive to injection delivery via standard wells. It is anticipated that the emplacement material will include a combination of Ferroblack®-H and sand slurry that can be propagated into discrete intervals to improve hydraulic communication in low permeability soils and provide a lasting source of treatment reagent for Cr(VI) reduction. Observations during the Phase I program will be used to refine the injection design approach, which can then be used to adapt the Phase II program based on the supplemental lithologic and Cr distribution information obtained. In advance of performing these activities, a modification to this PBR will be submitted to detail the specific method of delivery, objectives, implementation design and reagent use, and any changes to the monitoring program.

### 3.2.2 Reagent Selection and Dosing Strategy

In support of sustaining ISAB treatment mechanisms during active operation and post-IRM monitoring phases, multiple carbon substrates may be utilized. These will include dissolved-phase organic carbon materials (e.g., molasses) that can be easily distributed in the subsurface and longer lasting materials that can provide extended longevity following injection (e.g., EVO). Like other operational decisions, substrate selection will be an adaptive consideration, with decisions based on field information obtained during IRM Phase II.

During system operation and injection, it is assumed that organic carbon will be diluted with either treated groundwater from the WTP or the potable water supply and dosed via the recirculation stream for approximately 6 hours per day. For the other 18 hours of daily operation, injections will continue using either treated or potable water but without substrate dosing. Modifications to the dosing timing and reagent strength will be supported by ongoing operational monitoring (Section 4) to strike an appropriate balance between sustaining overall injectability, limiting biofouling and potential back pressure generation related to fermented gas generation, and achieving subsurface TOC distribution.

A combination of ISAB substrates is considered for use during Phase II. Phase II operations will be initiated using molasses as the organic carbon substrate consistent with the previous ISAB pilot test and the Phase I IRM program. Over the course of operation, EVO will be considered for use during late-stage recirculation to provide a longer-term source of organic carbon. While pulsed operation is anticipated, it is assumed, for PBR approval purposes, that the average organic carbon dosing over the course of the 12-month Phase II program is 0.5% by volume. Based on the projected total recirculation volume of 31.5 million gallons of groundwater, the organic carbon demands for Phase II will be no more than 158,000 gallons of substrate (either molasses, EVO, or a combination of both). As specified above, the actual dosing strength of these organic carbon substrates, the dosing durations per day (or per week), and the timing of molasses and EVO use will be determined based on monitoring observations.

Reagent flexibility is considered a key consideration for maximizing overall treatment during the IRM program. While the carbon substrates above will serve as the primary reagents for use, other reagents

are being included in this PBR to allow flexibility in the event that unique areas of the site are better suited to their application. As described in Section 2.2.2, both FerroBlack®-H and CaSx were used to achieve treatment during pilot test activities, and these reagents are retained for potential consideration during Phase II. CaSx could be delivered via the recirculation network as a soluble reagent for ISCR in select areas of Site 114 in lieu of or prior to use of a carbon substrate. In addition to these two reagents, ferrous sulfate may also be used as a supplement to the carbon substrate source to provide additional iron and sulfide to further enhance Cr abiotic reduction mechanisms. As applicable, other equivalent reagents capable of reducing Cr may also be considered during the Phase II IRM and if used, would be detailed in a modification to this PBR.

The SDSs for molasses, EVO, FerroBlack®-H, CaSx, and ferrous sulfate are included in **Appendix D**.

### 3.2.3 Injection and Extraction Well Flow Rates and Operating Sequencing

Consistent with the dynamic management approach discussed in Section 3.1.1 and **Appendix C**, operation of the individual injection and extraction wells will be modified based on routine performance data reviews reliant on both operational and treatment monitoring (Section 4) and updates to the dynamic groundwater and solute transport flow model. The sequencing of well operations are planned as part of three, 8-week steps to enable carbon distribution across the southern portion of Site 114 within the first 6 months. As executed during Phase I, the duration of these steps may be extended based on observed carbon reagent distribution and Cr reduction performance. Once the three steps are complete, it is anticipated that ongoing groundwater extraction and carbon delivery will be performed for the duration of the 12-month period to sustain treatment. Data collected over the course of operation will be used to adapt the overall program based on observed aquifer response and a focus on maximizing the extent of distribution achieved.

Injection well operational sequencing steps and modification may include the following:

- Injection rates in individual injection wells may be reduced or temporarily stopped to alter the hydraulic gradients and stresses applied to the intermediate and deep aquifers. As previously discussed, injection rates may also be reduced to focus available recirculation water on other well locations.
- The timing, duration, and dosing of carbon amendment pulsing may be adjusted to maximize sustainable flow rates and enhance carbon amendment distribution.
- Injection wells may temporarily or permanently be converted to extraction wells to enhance hydraulic control, mass removal, and/or overcome aquifer heterogeneities.

Similarly, individual extraction well operational modifications may include the following:

- Adjustment of extraction rates to optimize mass recovery, hydraulic control, overcome aquifer heterogeneities, and optimize carbon amendment distribution.
- Temporarily or permanently stop extraction operations if carbon amendment breakthrough is observed. Cessation of extraction operations will limit carbon loading to the treatment system and will prevent removal of the carbon substrate from the aquifer. In these instances, other extraction wells will be brought online to sustain the recirculation process and maintain overall recirculation water demands.

Injection wells positioned within the northern and southeastern treatment areas that are not being actively utilized as part of injection operations may be sampled as temporary monitoring wells to evaluate subsurface carbon distribution and to support decisions related to injection well sequence timing. Data from these wells may also be collected after injections have been completed to evaluate TOC longevity and to determine the timing of supplemental delivery, as necessary.

### 3.2.4 Well Development and Fouling Management

Arcadis' experience from Phase I and other similar groundwater recirculation and injection systems underpins the importance of a systematic fouling management plan. This is particularly important for both conveyance infrastructure and injection wells, where mixing of water with a varied range in redox potential and with organic carbon amendment can promote the formation of biofilms and/or metal precipitation. Biofilms and metal precipitation can be associated with a reduction in injection rates. During Phase I, the daily organic carbon pulsing program was effective in limiting the build-up of biological growth within the injection well network, but routine fouling was encountered in above-grade conveyance lines and fittings. Mitigation activities were required to address biofouling during warmer periods of the year and following transient upsets at the WTP. Several methods have been identified as part of the Phase II IRM to limit the impact of fouling on system shutdown, which include the use of potable water as an alternative reinjection source, additives to the WTP (e.g., chlorine) and the carbon dosing system (e.g., biocide), and use of a proactive injection well redevelopment scheme to prolong injection well and conveyance line performance. Injection well redevelopment may also include physical scrubbing, surging, and jetting of the well with or without the addition of chemicals/pH adjustments to remove biofilm and metal precipitates. Consistent with the adaptive management plan, the schedule for redevelopment of certain wells may be adjusted based on operational data (e.g., observed injection flow rates and wellhead pressures).

### 3.2.5 Well Network Optimization

Additional or replacement wells may be installed as the IRM Phase II progresses. The wells may include both injection and extraction wells with the intent of:

- Replacing destroyed or severely fouled wells.
- Enhancing hydraulic control, Cr recovery, or carbon amendment distribution in areas where performance is observed to be limited.

Additional wells may also be added to increase the vertical distribution of amendment by targeting depth intervals not sufficiently addressed by the initial injection/extraction well network.

### 3.2.6 Waste Disposal

Soil cuttings and drilling mud generated from well installation will be containerized in properly labeled 55-gallon drums or larger containers and disposed of at an appropriate off-site disposal facility using existing investigation-derived waste (IDW) profiles for Site 114. Purged water from well development and groundwater sampling activities will be temporarily stored in tanks and transferred to the treatment system following sufficient time for solids to settle. The settled solids will be disposed of at an appropriate off-site

disposal facility. Groundwater will be treated before being re-injected or discharged to the sewer. Sludge or filter cake generated from this process will be disposed of at an appropriate off-site disposal facility.

# 4 IRM MONITORING PROGRAM

The groundwater monitoring program for the IRM Phase II has been developed to support ongoing evaluation of Cr treatment effectiveness, to provide feedback related to Phase II recirculation operations, and to support continuous adaptation and optimization of the recirculation program. IRM Phase II monitoring activities are proposed as part of four primary categories to support treatment assessment and performance optimization, including 1) baseline sampling, 2) operational monitoring, 3) treatment monitoring, and 4) post-treatment monitoring.

A combination of both new and existing monitoring wells will be incorporated as part of each of these four monitoring categories. A list of new and existing monitoring wells (included in each of these monitoring categories for the intermediate and deep water-bearing zones) are provided in **Table 2**, and the monitoring well network is shown on **Figure 12** for the intermediate zone and **Figure 13** for the deep zone. A summary of the overall Phase II monitoring program is provided in **Table 3**. In addition to these well locations, select Phase II extraction and injection wells may also be periodically added into the sampling program to supplement the dedicated monitoring well network locations.

The details of the groundwater monitoring program are discussed in the sections below.

## 4.1 Baseline Sampling

Prior to the startup of Phase II operations but following the installation of the remediation well network and new monitoring well locations, samples will be collected for baseline analysis from new well locations to establish the starting conditions for IRM treatment performance review. In accordance with **Table 3**, baseline samples will be collected for TAL metals (total and dissolved); Cr(VI) (total and dissolved); key geochemical parameters (sulfate/sulfide and methane); TOC, field parameters (pH, specific conductivity, DO, ORP, turbidity, and temperature); and depth to groundwater. A summary of the monitoring wells included in the baseline sampling event is provided in **Table 2** along with all the new injection and extraction wells.

Baseline samples will be collected using the low-flow sampling method and select wells may be sampled at 5-foot intervals. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved TAL metals and dissolved Cr(VI) analyses will be field filtered using in-line 0.45 micrometer (µm) filters.

## 4.2 Operational Monitoring

The operational monitoring program will be utilized to assess ongoing remedial system performance in support of guiding potential modifications to injection and extraction flow rates, well balancing, carbon dosing and timing, and to pre-emptively guide potential biofouling management and well redevelopment. Operational monitoring will yield information pertaining to the sustainable recirculation flow rates, will confirm that wellhead injection pressures are within an appropriate range, will be useful to evaluate hydraulic influence of extraction and injection operations, and will confirm overall aboveground treatment

system effectiveness in accordance with the WUR permit. Collectively, these data will be used to guide adaptive system operations, routine adjustments, and overall optimization.

Depending on the parameters, operational monitoring will be performed at variable frequencies (weekly, biweekly, or monthly), as necessary, over the course of operation (**Table 3**). A summary of the well locations included as part of the operational monitoring program is provided in **Table 2**. Measurements may be periodically performed more frequently than specified in **Table 3** to support potential troubleshooting activities over the course of operation. Given the adaptive nature of the recirculation program and the sequencing of different groupings of injection and extraction wells over the course of operation, it is anticipated that the operational sampling frequency of existing monitoring wells will be adapted over time. As an example, monitoring wells located within the northernmost area of Site 114 are most relevant for operational monitoring during the first step of recirculation activities. Following this initial period and the transition to more southerly injection wells, the frequency and parameter list of the initial monitoring locations may be reduced to maintain remedial efficiency, as applicable.

For operational monitoring, analytical data and field parameter measurements for extracted and treated groundwater will be collected at operating extraction wells from sampling ports located at the wellheads or at the influent to the water treatment system. When collected from dedicated sampling ports, samples will be collected via grab sampling techniques. For individual well locations, samples will be collected using the one-volume purge sampling method (Arcadis 2017). The one-volume technique will entail dedicated tubing deployed to the middle of the screen intervals in each well for purging and sampling. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system.

## 4.3 Treatment Monitoring

Overall Phase II remedial performance will be documented via ongoing treatment monitoring over the course of the 12-month program. Sampling parameters will be collected to verify organic carbon distribution, assess the development of reduced geochemical groundwater conditions within the subsurface, and confirm corresponding declines in total Cr and Cr(VI). The development of the reactive zone confirmed via treatment monitoring activities will be used to guide carbon substrate dosing strength and frequency based on the observed subsurface response and confirm that reactive zone propagation has been achieved prior to transition of operating recirculation wells to subsequent steps. A summary of the analytical and field parameter measurements for treatment sampling is provided in **Table 3**, and well locations included in the overall treatment monitoring program are included in **Table 2** and on **Figures 12** and **13**.

Similar to the operational monitoring specifications, treatment monitoring parameters will be collected at a specified frequency based on the relevance of a given parameter to operation and optimization activities. TOC and field parameter sampling is proposed most frequently (biweekly to monthly) to effectively gauge propagation of both carbon substrate and geochemical influence within the subsurface. Total Cr and Cr(VI) and select geochemical parameters ([dissolved] Fe[II], dissolved manganese, sulfate) will be collected monthly to enable the collection of at least one to two samples between recirculation well steps. Methane sampling is also proposed, albeit less frequently, to confirm the overall extent of reduced groundwater conditions. Similar to the sampling frequency considerations presented for the operational

monitoring program, select well locations or parameters may be collected more or less frequently for system optimization purposes, as applicable.

Treatment monitoring samples will be collected using the low-flow sampling method and select wells may be sampled at 5-foot intervals. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved total Cr and Cr(VI) analyses will be field filtered using in-line 0.45 µm filters.

Data collected as part of the treatment monitoring program will be used to confirm treatment performance in areas undergoing active carbon recirculation and to confirm the longevity of TOC availability and treatment permanence as recirculation activities transition to other areas of Site 114. Data collected between recirculation cycles will also be used to determine whether subsequent carbon substrate delivery is required during the 12-month Phase II period. These decisions will be guided based on observed TOC strength, its longevity in the subsurface, and the extent of observed Cr reduction.

## 4.4 Post-Treatment Monitoring

Following the 12-month Phase II operational program, post-treatment monitoring will be used to document overall Cr treatment performance, confirm the residual reactive zone reduction capacity (via residual TOC and reduced geochemistry species), and develop an appropriate data set to demonstrate ongoing natural attenuation of any residual total Cr and Cr(VI). Post-treatment sampling will be performed in accordance with **Table 3** and at well locations shown in **Table 2**.

Treatment monitoring samples will be collected using the low-flow sampling method and select screen locations with wells will be sampled at 5-foot intervals. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system or containerized and disposed of off-site, as appropriate. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved total Cr and Cr(VI) analyses will be field filtered using in-line 0.45 µm filters.

Post-treatment sampling activities will be performed on a quarterly basis over a total duration of 2 years.

# 5 SCHEDULE AND REPORTING

Details of the supplemental pre-design testing, well and system installation, system operation, and performance monitoring results associated with the IRM Phase II program will be documented as part of a quarterly technical status reports submitted to NJDEP. These quarterly status reports will include succinct, high-level summaries of activities performed, data collected, adaptive steps taken to modify or optimize Phase II treatment, and an overview of activities planned for the subsequent quarter.

Upon approval of this IRM Phase II Work Plan, the PBR Authorization by NJDEP, and receiving all the applicable permits required to conduct the field work detailed in this document, PPG will proceed with startup of the IRM Phase II program. IRM infrastructure construction (e.g., well installation, water treatment plant modification, conveyance piping installation) may be initiated prior to final approval to expedite elements of the project schedule, as necessary. The IRM Phase II operation is anticipated to start in the second quarter of 2019 and last for a duration of up to approximately 12 months, followed by a post-operational monitoring period of 2 years. As-built layouts for the IRM Design will be provided within the appropriate quarterly status report.

The schedule for implementation of the IRM Phase II program may be adjusted based on regulatory review and approval of the PBR Authorization and the IRM Phase II Work Plan.

**IRM Phase I and II Monitoring Well Details**
**Groundwater IRM: Phase II Design and PBR Authorization Request**
**PPG Garfield Avenue Group Sites, Jersey City, New Jersey**

**Notes:**
1 - The total depth of new wells and number of screens at each location are tentative and may be adjusted based on field observation.
* PPG will prepare and submit a revised monitoring well network table once proposed extraction, injection, and monitoring wells are installed
bgs - below ground surface
bTOC - below top of casing
ft - feet
I/D - intermediate/deep
in - inches
IRM - interim remedial measures
NAVD88 - North American Vertical Datum, 1988
PBR - Permit-by-Rule
PPG - Piitsburgh Paint and Glass
TBD - to be determined
X - selected
-- not available

**Table 3**
**IRM Phase I and II Groundwater Monitoring Program**
**Groundwater IRM: Phase II Design and PBR Authorization Request**
**PPG Garfield Avenue Group Sites, Jersey City, New Jersey**

ARCADIS Design & Consultancy for natural and built assets

| Monitoring Program | Monitoring Well Network | Monitoring Parameters | Monitoring Frequency |
|---|---|---|---|
| Baseline Monitoring | New extraction, injection monitoring wells and existing monitoring wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature<br>2. **Lab Analytical**: Total/dissolved TAL metals, total/dissolved Cr(VI), TOC, sulfate/sulfide, and methane | Prior to operation start |
| Operational Monitoring | New extraction and monitoring wells; existing shallow, intermediate, and deep monitoring wells; and system sampling port (influent and effluent) | 1. **Field Parameters**: DTW | Weekly - Biweekly |
| | | 2. **System Parameters**<br>- Injection / extraction well flow rates | Weekly |
| | | - Wellhead pressures | Weekly |
| | | - Water treatment system monitoring | Weekly - Monthly (as appropriate) |
| Treatment Monitoring | New extraction and monitoring wells and existing intermediate and deep monitoring wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature | Biweekly - Monthly |
| | | **2. Lab Analytical:**<br>- Total/dissolved Cr and Cr(VI) | Monthly |
| | | - TOC | Biweekly - Monthly |
| | | - Supplemental geochemical parameters (sulfate, ferrous [dissolved] iron, dissolved manganese) | Monthly |
| | | - Methane | Monthly - Quarterly |
| Post-Treatment Monitoring | New monitoring wells and existing shallow, intermediate, and deep monitoring wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature<br>2. **Lab Analytical**: Total/dissolved TAL metals, total/dissolved Cr and Cr(VI), VOCs, SVOCs, TOC, sulfate/sulfide, dissolved iron, dissolved manganese, and methane. | Quarterly following system shutdown for up to 2 years |

**Notes:**

1. The monitoring locations, parameters, and frequencies provided in this table serve as general guidance for IRM-related monitoring activities and may be adjusted or changed based on IRM Phase I performance, injection and extraction areas in operation, and observed monitoring results.
2. Dissolved metal samples are to be field filtered prior to sample collection.

Cr - chromium
Cr(VI) - hexavalent chromium
DO - dissolved oxygen
DTW - depth-to-water
IRM - Interim Remedial Measures
ORP - oxidation-reduction potential
PBR - Permit-by-Rule
PPG - Pittsburgh Paint and Glass
SVOC - semi-volatile organic compound
TAL - target analyte list
TOC - total organic carbon
VOC - volatile organic compound

Notes:

1. Concentrations are shown in the unit of micrograms per liter (µg/L).
2. The New Jersey Department of Environmental Protection's Groundwater Quality Standard for chromium is 70 µg/L.
3. Isopleths are drawn based on the highest concentration obtained from monitoring wells with multiple sampling intervals.
4. Elevation vertical datum is NAV D88 in U.S. survey ft.
5. Where data was not collected in October 2018, the most recent data from each well were used.

ft - feet
NAV D88 - North American Vertical Datum of 1988
IRM - Interim Remedial Measures
R I – Remedial Investigation
VAP - Vertical Aquifer Profiling

# APPENDIX A

## Draft Public Notice

## DRAFT PUBLIC NOTICE

Take notice that, as part of the remediation of Garfield Avenue Site 114 and Former Halladay Street Gas Works at 900 Garfield Avenue, Block: 21501 Lots: 16,17,18, 19, 20, in the City of Jersey City, Hudson County, New Jersey, a proposal has been submitted to the New Jersey Department of Environmental Protection (Department) to discharge to groundwater in accordance with a permit issued pursuant to the provisions of the New Jersey Water Pollution Control Act, New Jersey Statutes Annotated (N.J.S.A.) 58:10A-1 et seq., the New Jersey Pollutant Discharge Elimination System, New Jersey Administrative Code (N.J.A.C.) 7:14A; the Ground Water Quality Standards, N.J.A.C. 7:9C; and the Technical Requirements for Site Remediation, N.J.A.C. 7:26E. The Department's Site Remediation Program is reviewing the proposal to discharge to groundwater for the purpose of remediating a contaminated site with the program interest # G000008791.

Brief description of the proposed discharge: The Phase II Interim Remedial Measure will be implemented at Site 114, which is located at 900 Garfield Avenue in Jersey City, Hudson County, New Jersey. The site is located on the Jersey City peninsula, approximately midway between the Passaic River and Hackensack River junction to the west (approximately 1.8 miles) and the upper bay/mouth of the Hudson River to the east (approximately 1.6 miles). The local overburden geology is generally consistent with the regional geologic mapping and includes approximately 16 feet of poorly sorted fill materials over organic rich meadow mat. The meadow mat occurs over most of the site and marks the transition from the shallow fill aquifer to the intermediate depth and deep aquifers, although in some areas the meadow mat is absent. The pilot study will include a combination of groundwater extraction, treatment, and reinjection to achieve in situ anaerobic bioprecipitation (ISAB) and in-situ chemical reduction (ISCR). In the overburden, ISAB will be achieved by injecting organic carbon substrate (e.g., molasses and/or emulsified vegetable oil [EVO]) to establish geochemical reducing conditions to stimulate a native microbial community for reducing hexavalent chromium (Cr[VI]) to trivalent chromium (Cr[III]), which will eventually be precipitated and permanently fixed in soil formation. At the same time, distribution of injected organic carbon substrate and expansion of established reducing conditions (ISCR) will be supported with a dynamically operated well network (i.e., alternately operating wells for extraction and/or injection, as needed) and groundwater recirculation (i.e., reinjecting of extracted groundwater after aboveground treatment). A copy of this public notice has been sent to the Municipal Clerk and the designated Local Health Official for Jersey City and Hudson County, New Jersey.

A copy of the discharge to groundwater proposal is available from the person responsible for conducting the remediation (Mark Terril, One PPG Place, Pittsburgh, PA 15222), or as part of the administrative record, which is on file at the offices of the Department, Site Remediation Program, located at 401 East State Street, Trenton, Mercer County, New Jersey. The file may be reviewed under the New Jersey Open Public Records Act (OPRA), N.J.S.A. 47:1A-1 et seq. Information regarding the OPRA procedures is available at http://www.state.nj.us/dep/opra/oprainfo.html.

Interested persons may submit written comments regarding the discharge to groundwater proposal to the Department at the address listed below and to the owner or operator of the facility: Richard Feinberg, 900 Garfield Avenue, Jersey City, NJ, 07305. All comments shall be submitted within 30 calendar days after the date of this public notice or the end of any public hearing that the Department may schedule that occurs after that date. All persons who believe that the discharge to groundwater proposal is

inappropriate, must submit all reasonably ascertainable issues in writing to the Department, with all supporting material, by the close of the public comment period. The Department will consider all public comments that relate to the discharge to groundwater proposal, provided that the Department receives the comments by the close of the public comment period. After the close of the public comment period, the Department will render a decision regarding the proposed discharge to groundwater.

The Department will respond to all significant and timely comments with its decision regarding the discharge to groundwater proposal. Each person who has submitted written comments will receive notice of the Department's decision.

Any person may request in writing that the Department hold a non-adversarial public hearing on the discharge to groundwater proposal. This request shall state the nature of the issues to be raised in the proposed hearing and shall be submitted within 30 calendar days of the date of this public notice to the address cited below. A public hearing will be conducted whenever the Department determines that there is a significant degree of public interest in the discharge to groundwater decision. If a public hearing is held, the public comment period in this notice shall automatically be extended to the close of the public hearing.

Comments and written requests for a non-adversarial public hearing shall be sent to:

ARCADIS Design & Consultancy for natural and built assets

**Notes:**

| | |
|---|---|
| < 3.0 U | Constituent not detected at concentrations greater than the laboratory detection limit. |
| 13.6 | Constituent detected at concentrations above the laboratory detection limit. |
| **311** | Constituent detected at concentrations above the applicable NJDEP GWQC. |
| -- | data not available |

**Abbreviations:**

| | |
|---|---|
| CASRN | Chemical Abstracts System Registration Number |
| D | dissolved |
| FD | Field duplicate sample |
| mg/l | milligrams per liter |
| mS/cm | millisiemens per centimeter |
| mV | millivolts |
| NA | Not Analyzed |
| PPG NJDEP GWQC | New Jersey Department of Environmental Protection Groundwater Quality Criteria |
| s.u. | standard pH units |
| T | total |
| µg/l | micrograms per liter |

**Data Qualifiers:**

| | |
|---|---|
| U | The compound was analyzed for but not detected. The associated value is the compound quantitation limit. |
| B | The compound has been found in the sample as well as its associated blank, its presence in the sample may be suspect. |
| E | The compound was quantitated above the calibration range. |
| D | Concentration is based on a diluted sample analysis. |
| J | The compound was positively identified; however, the associated numerical value is an estimated concentration only. |
| J+ | The result is an estimated quantity, but the result may be biased high. |
| J- | The result is an estimated quantity, but the result may be biased low. |
| UJ | The compound was not detected above the reported sample quantitation limit. However, the reported limit is approximate and may or may not represent the actual limit of quantitation. |
| UB | Compound considered non-detect at the listed value due to associated blank contamination. |
| R | The sample results are rejected. |

## Recirculation Flow and Solute Transport Modeling

## Recirculation Flow and Solute Transport Modeling

The existing groundwater flow and solute transport model for Site 114 was re-evaluated based on the collection of new data during the installation and operation of the Phase I IRM system. The flow model calibration was initially verified based on observed water levels under active Phase I IRM system rates. Next, the solute transport model was evaluated by comparing the observed propagation of reagent (total organic carbon [TOC]) and reducing condition observed during Phase I operations to the previously simulated intermediate and deep reactive zones after 6 months of Phase I IRM operation. The groundwater flow and solute transport model was then updated to better match observed Phase I observations. The updated groundwater flow and solute transport model was then used to assess the necessary spacing, orientation, and operational sequencing of the Phase II well network. The modeling approach allowed verification of the combination of extraction and injection at Site 114 that avoids excessive hydraulic mounding within the sheet pile walls while achieving organic carbon distribution during the Phase II operational timeframe. Finally, this model will serve as a tool for future optimization of the Phase II program based on additional groundwater extraction and injection information generated over the course of operation.

## Hydrogeology Implications for Groundwater Recirculation

The local hydrogeology discussed in Section 2.3 has been considered when designing and constructing the injection and extraction well network for the Phase II IRM. Several key geologic conditions for the design include the following:

- Utilization of fine-grained soils associated with the meadow mat (where present) to ensure a good seal between the shallow and intermediate aquifers.
- Consideration of the hydraulic control necessary for both higher chromium (Cr) mass and volumetric flux within the intermediate water-bearing zone.
- The expected contrast in hydraulic conductivity between the intermediate and deep water-baring zones that may require discretely-screened remediation wells to address both intervals.

Existing Phase I hydraulic information and observed reactive zone distribution within Site 114 have been utilized to develop the Phase II conceptual well network.

## Model Development and Calibration

The simulation program MODFLOW was selected for the construction of the numerical groundwater flow model at the site. MODFLOW is a publicly available groundwater flow simulation program developed by the U.S. Geological Survey (McDonald and Harbaugh 1988). MODFLOW simulates transient or steady-state, saturated groundwater flow in three dimensions. The program is designed to simplify the specification of boundary conditions by designing the data input to align with common field variables. The boundary conditions supported by MODFLOW include specified head, precipitation recharge, injection or extraction wells, evapotranspiration, horizontal flow barriers, drains, and rivers or streams. Aquifers simulated by MODFLOW can be confined, unconfined, or convertible between conditions. For the site, which consists of a heterogeneous geologic system with variable unit thicknesses and boundary conditions, MODFLOW's three-dimensional capability and boundary condition versatility are essential for the proper simulation of groundwater flow conditions.

MODFLOW uses the method of finite differences to solve the equations of groundwater flow. Using a block-centered finite-difference approach, MODFLOW replaces the continuous system represented by the equations of flow with a system of discrete blocks in space. The solution of the finite-difference equations produces time-varying values of hydraulic head at each of the discrete points representing the real aquifer system.

The model extents are limited to the Site 114 boundary, which follows the perimeter sheet pile walls that provide effective hydraulic control for the majority of the site. The model is composed of four vertical layers that discretely represent the shallow fill, meadow mat, and intermediate and deep water-bearing zones. The base of the model represents the contact between the bottom of the deep aquifer and the underlying till and/or bedrock. The thickness of each model layer was initialized based upon hydrogeologic unit contacts identified in site boring logs, geophysical surveys, and interpolated cross-sections. Hydraulic parameters, such as hydraulic conductivity and recharge, were assigned within ranges of observed values based on site slug tests, aquifer tests, and literature values. Model boundary conditions include no-flow cells to represent the perimeter sheet pile walls, hydraulic flow boundaries to represent interior sheet pile walls, head boundaries to represent the portions of the site perimeter where the existing sheet pile walls do not fully extend to the underlying till and/or bedrock, and wells to represent the installed Phase I IRM remedial injection and extraction wells. Hydraulic flow barriers representing the interior sheet piles in the northwestern portion of the Site were removed consistent with the removal of the sheet piles in this area. The model domain extents, updated boundary conditions, and Phase I IRM wells are shown in **Figure 1**. The model was qualitatively calibrated to the average Phase I IRM operational conditions, accounting for a 3-foot head difference from shallow to intermediate water-bearing zones across the meadow mat. No further modifications were made to the hydraulic conductivity values or distribution were deemed necessary.

Upon completion of the groundwater flow model update, the solute transport modeling was performed using the modular three-dimensional transport model referred to as Modular 3-D Transport Model (MT3D). MT3D was originally developed by Zheng (1990) at S.S. Papadopulos & Associates, Inc. for the Robert S. Kerr, Environmental Research Laboratory of the U.S. Environmental Protection Agency (USEPA). The MT3D code uses the flows computed by MODFLOW in its transport calculations. MT3D also uses the same finite-difference grid structure and boundary conditions as MODFLOW, simplifying the effort to construct the solute transport model. MT3D is regularly updated (Zheng and Wang 1999), and the most recent version is referred to in the literature as MT3D Multi-Species (MT3DMS), where MS denotes the Multi-Species structure for accommodating add-on reaction packages. MT3DMS has a comprehensive set of options and capabilities for simulating advection, dispersion/diffusion, and chemical reactions of contaminants in groundwater flow systems under a range of hydrogeologic conditions. Recent updates to MT3DMS have included the dual-domain formulation and the ability to incorporate site-specific processes.

To represent the development of the reactive zone over time, the injection of a carbon substrate was simulated. The carbon substrate is not readily sorbed in the subsurface so there was no sorption parameter simulated. Based on the previous data obtained during in situ anaerobic bioprecipitation pilot testing, a conservative (i.e., faster) carbon degradation half-life of 20-days was simulated. The original solute transport model is simulated as dual domain with an average mobile porosity of 10% and immobile porosity of 25% in all model layers. However, based on the limited observed distribution of the carbon substrate and reactive zone in the deep aquifer (Model Layer 4), the mobile and immobile porosity was systematically adjusted until the simulated carbon substrate/reactive zone distribution better matched the observed distribution during Phase I IRM operations. The final mobile and immobile porosities of model

layer 4 were set to 15% and 20%, respectively. No further modifications were made to the solute transport model parameters or distribution. The simulated 6-month Phase I IRM reaction zone distribution is presented in **Figure 2**.

For evaluation of the proposed Phase II IRM, a constant organic carbon injection concentration of 100 milligrams per liter (mg/L) was assumed so it can be easily scaled to represent different proposed injection concentrations. While constant carbon delivery was assumed for model purposes, it is expected that Phase II operations will rely on a pulsed carbon delivery similar to Phase I. The individual Phase II carbon pulses will include a range of TOC concentrations between 1,000 to 7,000 mg/L during each of the operational steps, so the 100 mg/L assumption used in the model is considered a low estimate of total Phase II delivery for conservative purposes.

## Remedy Simulation

The updated groundwater flow and solute transport model was utilized to iterate a combination of remedial well infrastructure, flow rates, and operational sequencing to establish an optimal remedy design of the Phase II IRM. The injection and extraction rates simulated in this Phase II evaluation are based on observed Phase I extraction and injection well operational rates and assume Phase I was completed. The final Phase II IRM design consists of 137 new remediation well locations that will be multipurpose and used for either injection or extraction purposes based on the specific operational step. These new wells will supplement 12 additional Phase I wells already installed within northern Site 114 and used as part of the Phase I IRM (**Figure 13**). These locations will supplement 12 existing extraction wells located in the northern half of Site 114 that were operated during the Phase I program. New well locations were chosen based on the observed Cr distribution from October 2018 in the intermediate and deep water-bearing zones. The injection wells are located in the northern half of Site 114 and in the southeastern corner of Site 114. Dedicated Phase II extraction wells are located in the center of Site 114 spanning east-west and are in an area of elevated Cr concentrations to support mass removal during the early steps and then allow reagent introduction during late-stage Phase II treatment. At each well location, hydraulic simulations were performed to allow access to both model layers 3 and 4 based on their relative hydraulic conductivity. This process allows development of a total number of well locations for the PBR and allows for modification of the actual number of discrete well intervals necessary based on observations pertaining to the local aquifer heterogeneity, saturated thickness, and Cr concentrations during confirmatory sampling and construction activities.

Iterations of the site-specific injection and extraction flow rates and the Phase I well network indicated that a combined injection and extraction rate of 21 gallons per minute (gpm) in the north and 12 gpm in the southeast can achieve organic carbon distribution within the target Site 114 treatment areas during the first 6-month period. While this flow rate was acceptable for modeling purposes, it is anticipated that wells will behave differently based on unique geologic heterogeneities in different areas of the site. It is also assumed that where achievable, injection and extraction rates will be increased to maximize the total quantity of groundwater extracted and injected, within permit specifications. The design simulation entails initiation of injection activities within the northern end of Site 114 followed by gradual southward shifts in operating wells. For the southeastern area, injections would initiate in the westernmost portion of the injection network and proceed gradually eastward during 8-week cycles. This modeled sequencing allows for complete carbon coverage and reactive zone development for Cr reduction throughout the Phase II injection area. **Figure 3** shows the simulated well locations and rates over the simulated 6-month period. **Figure 4** shows the active injection and extraction wells locations during each of the three stages of remedy operation.

The resulting reactive zone development at weeks 8, 16, and 24 (days 56, 112, and 168) is shown on **Figure 5** and **Figure 6** for the intermediate and deep water-bearing zones (layers 3 and 4), respectively. This reactive zone is defined as the extent of the simulated carbon substrate concentration above a relative concentration of 0.1%, which reflects the combined influence of TOC and reduced groundwater geochemistry footprints. This allows for the simulated carbon concentration results to be directly scalable to the final proposed injection concentrations to evaluate carbon concentration distributions during active remedy conditions. The simulated reactive zone development indicates that within a 6-month period, the Phase II area will be effectively addressed with either available TOC or reduced metal species – both of which work to reduce Cr.

To evaluate the drawdown and mounding, the simulated active remedy transient water levels were also reviewed in detail. The simulated steady-state water level starting conditions for model layers 3 and 4 are shown on **Figure 7**. The simulated active remedy transient water levels for model layers 3 and 4 at weeks 8, 16, and 24 are shown on **Figures 8** and **9**, respectively. These transient water levels were then directly compared to the starting steady state water levels to determine the relative hydraulic mounding and drawdown that occurs during remedy operation. **Figures 10** and **11** show the relative changes in water levels over time for model layers 3 and 4, respectively. The maximum hydraulic mounding is approximately 3.5 feet in both model layers 3 and 4. This indicates that simulated mounding water levels will not exceed land surface and that a neutral to downward vertical gradient is preserved between the intermediate and deep aquifers.

## Model Update

Through additional hydrogeologic testing, hydraulic monitoring, and water quality monitoring during remedial well infrastructure installation and Phase II operation, the groundwater flow and solute transport model can be updated periodically to more accurately reflect encountered conditions. This will allow the model to be further used as a predictive tool to evaluate remedy performance and assist in providing recommendations for optimization of the remedial system (i.e., injection/extraction rates and frequency, carbon dosing frequency and concentration, and need for provisional wells).

As with all mathematical models of natural systems, the groundwater flow and solute transport model is limited by factors such as scale, accuracy of the estimated hydraulic properties and/or boundary conditions, and the underlying simplifications and assumptions incorporated into the model. These factors result in limitations to the model's appropriate uses and to the interpretations that may be made of the simulation results. The proposed remedy design and operation were based on the conceptual site model, calibrated groundwater flow model, the predictive solute transport modeling, and professional expertise related to similar remedial designs and modeling bases. This model is intended to serve as the initial basis for the Phase II IRM design, considering that additional data collection prior to and during the Phase II implementation will all be used to adapt and refine treatment operations.

## Section 2: HAZARD(S) IDENTIFICATION

**2.1 Hazard Classification:**

| | | |
|---|---|---|
| Health | Acute Oral Toxicity | Category 4 |
| | Acute Dermal Toxicity | Category 4 |
| | Acute Inhalation Toxicity | Category 4 |
| | Skin Corrosion/Irritation | Category 2 |
| | Eye Damage/Irritation | Category 2B |
| Physical | None | |

**2.2 Signal Word:** Warning

**2.2.1 Hazard Statement(s):**

Harmful if swallowed.
Harmful in contact with skin.
Harmful if inhaled.
Causes skin irritation.
Causes eye irritation.

**2.2.2 Symbol(s):**

**2.2.3 Precautionary Statement(s):**

**If swallowed**: Rinse mouth. Call a poison center/doctor/regional medical center if you feel unwell.
**If on skin**: Wash with plenty of water. Take off contaminated clothing and wash before reuse. Continue rinsing. Call a poison center/doctor/regional medical center if you feel unwell.
**If inhaled**: Remove person to fresh air and make comfortable for breathing. Call poison center/doctor/regional medical center if you feel unwell.
**If in eyes**: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. If eye irritation occurs: Get medical advice/attention.
Wash hands and face thoroughly with water after handling. Do not eat, drink or smoke when using this product.
Wear neoprene rubber chemical suit, gloves, goggles/full-face shield when handling product.
Avoid breathing product fume/gas/mist/vapors/spray.
Use only outdoors or in well-ventilated area.
Dispose of contents/container to chemical waste facility in accordance with local/regional/federal regulations.
Do not allow release to waterways (potential aquatic toxicity).

**2.3 Unclassified Hazard(s):** Aquatic toxicity.

**2.4 Unknown Toxicity Ingredient:** None

## Section 3: COMPOSITION/INFORMATION ON INGREDIENTS

**3.1 Chemical Ingredients** (See Section 8 for exposure guidelines):

| Chemical | Synonym Common Name | CAS No. | EINECS No. | % by Wt. |
|---|---|---|---|---|
| Calcium polysulfide, $CaS_x$ | Lime sulfur, calcium sulfide | 1344-81-6 | 215-709-2 | 24 - 29 |
| Water | Water | 7732-18-5 | 231-791-2 | Remaining % |

## Section 4: FIRST AID MEASURES

**4.1 Symptoms/Effects:**

Acute: Eye contact may cause eye irritation. Repeated or prolonged skin contact may cause skin irritation. Ingestion may irritate the gastrointestinal tract.

Chronic: No known chronic effects.

**4.2 Eyes:** Immediately flush with large quantities of water for 15 minutes. Hold eyelids apart during irrigation to insure thorough flushing of the entire area of the eye and lids. Obtain medical attention if irritation occurs.

**4.3 Skin:** Immediately flush with large quantities of water. Remove contaminated clothing under a safety shower. Continue rinsing. Obtain medical attention if irritation occurs.

**4.4 Ingestion:** If victim is conscious, give 2 to 4 glasses of water and induce vomiting by touching finger to back of throat. Obtain immediate medical attention.

**4.5 Inhalation:** Remove victim from contaminated atmosphere. If breathing is labored, administer oxygen. If breathing has ceased, clear airway and start CPR. Obtain immediate medical attention.

## Section 5: FIRE FIGHTING MEASURES

**5.1 Flammable Properties:** (See Section 9, for additional flammable properties)

**NFPA: Health – 2 Flammability – 0 Reactivity - 0**

Heating this product will evolve hydrogen sulfide vapors.

**5.2 Extinguishing Media:**

**5.2.1 Suitable Extinguishing Media:** Not flammable, use media suitable for combustibles involved in fire.

**5.2.2 Unsuitable Extinguishing Media:** Not applicable.

**5.3 Protection of Firefighters:**

**5.3.1 Specific Hazards Arising from the Chemical:**

**Physical Hazards:** Heating (flames) of closed or sealed containers may cause violent rupture of container due to thermal expansion of compressed gases.

**Chemical Hazards:** Heating causes release of hydrogen sulfide vapors. Vapors are irritating to eyes, skin and respiratory tract.

**5.3.2 Protective Equipment and Precautions for Firefighters:**

Firefighters should wear self-contained breathing apparatus (SCBA) and full fire-fighting turnout gear. Keep containers/storage vessels in fire area cooled with water spray.

## Section 6: ACCIDENTAL RELEASE MEASURES

**6.1 Personal Precautions:** Use personal protective equipment specified in Section 8. Isolate the release area and deny entry to unnecessary, unprotected and untrained personnel.

**6.2 Environmental Precautions:**

Keep out of “waters of the United States” because of potential aquatic toxicity (See Section 12).

**6.3 Methods of Containment:**

**Small Release:** Confine and absorb small releases on sand, earth or other inert absorbents.

**Large Release:** Shut off release if safe to do so. Dike spill area with earth, sand or other inert absorbents to prevent runoff into surface waterways (potential aquatic toxicity).

**6.4 Method for Cleanup:**

**Small Release:** For small areas shovel up absorbed material and place in drums for disposal as a chemical waste.

**Large Release:** Recover as much of the spilled product using portable pump and hoses. Treat remaining material as a small release (above).

## Section 7: HANDLING and STORAGE

**7.1 Handling:** Avoid contact with eyes. Use only in a well-ventilated area. Wash thoroughly after handling. Avoid prolonged or repeated breathing of vapors. Avoid prolonged or repeated contact with the skin.

**7.2 Storage:** Store in well-ventilated areas. Do not store combustibles in the area of storage vessels. Keep away from any sources of heat or flame. Store totes and smaller containers out of direct sunlight at moderate temperatures.

## Section 8: EXPOSURE CONTROLS/PERSONAL PROTECTION

**8.1 Exposure Guidelines:**

| Chemical | OSHA PELs | | ACGIH TLVs | |
|---|---|---|---|---|
| | TWA | STEL | TLV | STEL |
| Hydrogen sulfide | 20 ppm (Ceiling) | ---- | 1 ppm | 5 ppm |

**8.2 Engineering Controls:** Use adequate exhaust ventilation to prevent inhalation of product vapors. Keep eye wash/safety shower in areas where product is commonly handled.

**8.3 Personal Protective Equipment (PPE):**

**8.3.1 Eye/Face Protection:** Chemical goggles and a full face shield.

**8.3.2 Skin Protection:** Neoprene rubber gloves and suit should be worn to prevent repeated or prolonged contact with the liquid. Wash contaminated clothing prior to reuse.

**8.3.3 Respiratory Protection:**

Have self-contained breathing apparatus (SCBA), positive pressure, MSHA/NIOSH (approved or equivalent) available in case of spillage or equipment failure.

**8.3.4 Hygiene Considerations:**

Common good industrial hygiene practices should be followed, such as washing thoroughly after handling and before eating or drinking.

## Section 9: PHYSICAL and CHEMICAL PROPERTIES

| | |
|---|---|
| **9.1 Appearance:** | Ruby-red liquid |
| **9.2 Odor:** | Odor of rotten eggs |
| **9.3 Odor Threshold:** | 4.7 ppb (hydrogen sulfide) |
| **9.4 pH:** | 11.5 – 11.7, Typical |
| **9.5 Melting Point/Freezing Point:** | 18 to 25°F (-7.7 to -3.9°C), Typical |
| **9.6 Boiling Point:** | Not determined |
| **9.7 Flash Point:** | Not applicable |
| **9.8 Evaporation Rate:** | Not determined |
| **9.9 Flammability:** | Not applicable |
| **9.10 Upper/Lower Flammability Limits:** | Not applicable |
| **9.11 Vapor Pressure:** | Not determined |
| **9.12 Vapor Density:** | Not determined |
| **9.13 Relative Density:** | 1.27 (10.6 lbs/gal), Typical |
| **9.14 Solubility:** | Miscible |
| **9.15 Partition Coefficient:** | Data not available. |
| **9.16 Auto-ignition Temperature:** | Not applicable. |
| **9.17 Decomposition Temperature:** | Not determined. |
| **9.18 Viscosity:** | 2.95 cSt @ 20°C, 2.5 cSt @ 30°C. |

## Section 10: STABILITY and REACTIVITY

| | |
|---|---|
| **10.1 Reactivity:** | Strong oxidizers and acids. |
| **10.2 Chemical Stability:** | This is a stable product under conditions of ambient temperature and pressure. |
| **10.3 Possibility of Hazardous Reactions:** | Interaction with strong oxidizers, acids or acidic materials. |
| **10.4 Conditions to Avoid:** | Interaction with strong oxidizers or acidic materials (evolution of hydrogen sulfide vapors). |
| **10.5 Incompatible:** | Strong oxidizers can cause explosive mixtures if heated to dryness. Acids, acidic materials and dilution with water will cause the release of highly toxic hydrogen sulfide vapors. |
| **10.6 Hazardous Decomposition Products:** | Hydrogen sulfide and oxides of sulfur. |

## Section 11: TOXICOLOGICAL INFORMATION

| | |
|---|---|
| **11.1 Oral:** | Oral Rat $LD_{50}$: 820 mg/kg. |
| **11.2 Dermal:** | Dermal Rabbit $LD_{50}$: > 2,000 mg/kg. |
| **11.3 Inhalation:** | INH-Rat $LC_{50}$: 3.6 mg/L (4 hr. exposure). |
| **11.4 Eye:** | Data not available. |
| **11.5 Chronic/Carcinogenicity:** | Not listed in NTP, IARC or by OSHA. |
| **11.6 Teratology:** | Data not available. |
| **11.7 Reproduction:** | Data not available. |

**11.8 Mutagenicity:** Data not available.

## Section 12: ECOLOGICAL INFORMATION

**12.1 Ecotoxicity:** Green Algae, $EC_{50}$: 16.4 mg/l.

Water Flea, $EC_{50}$: 13.7 mg/l.

Bluegill, $LC_{50}$: 52.9 mg/l.

Fathead Minnow, $LC_{50}$: 42.9 mg/l.

Rainbow Trout, $LC_{50}$: 8.8mg/l.

**12.2 Persistence & Degradability:** No data is available.

**12.3 Bioaccumulative Potential:** This product is not bioaccumulative.

**12.4 Mobility in Soil:** No data available.

**12.5 Other Adverse Effects:** None

## Section 13: DISPOSAL CONSIDERATIONS

Consult federal, state and local regulations for disposal regulations.

## Section 14: TRANSPORT INFORMATION

**14.1 Basic Shipping Description:**

**14.1.1 Proper Shipping Name:** Calcium polysulfide solution *(Not regulated by DOT)*
**14.1.2 Hazard Classes:** Not applicable
**14.1.3 Identification Number:** Not applicable
**14.1.4 Packing Group:** Not applicable
**14.1.5 Hazardous Substance:** No
**14.1.6 Marine Pollutant:** No

**14.2 Additional Information:**

**14.2.1 Other DOT Requirements:**

**14.2.1.1 Reportable Quantity:** No
**14.2.1.2 Placard(s):** Not applicable
**14.2.1.3 Label(s):** Not applicable
**14.2.2 USCG Classification:** Not determined.

**14.2.3 International Transportation:**

**14.2.3.1 IMO:** Environmentally hazardous substance, liquid, n.o.s. (calcium polysulfide)

| | |
|---|---|
| **14.2.3.2 IATA:** | Non-hazardous under IATA regulations. |
| **14.2.3.3 TDG (Canada):** | Not regulated – See US DOT Section 14.1.1. |
| **14.2.3.4 ADR (Europe):** | Environmentally hazardous substance, liquid, n.o.s. (calcium polysulfide) |
| **14.2.3.5 ADG (Australia):** | Environmentally hazardous substance, liquid, n.o.s. (calcium polysulfide) |
| **14.2.4 Emergency Response Guide:** | Not applicable |
| **14.2.5 ERAP - Canada:** | Not applicable |
| **14.2.6 Special Precautions:** | Not applicable |
| **14.2.7 RR STCC** | 2899991 |

## Section 15: REGULATORY INFORMATION

### 15.1 U.S. Federal Regulations:

**15.1.1 OSHA:** This product meets the criteria of the Federal OSHA Hazard Communication Standard (29 CFR 1910.1200).

**15.1.2 TSCA:** Product is contained in USEPA Toxic Substance Control Act Inventory.

**15.1.3 CERCLA:** Reportable Quantity – Not applicable

**15.1.4 SARA Title III:**

**15.1.4.1 Extremely Hazardous Substance (EHS):** No

**15.1.4.2 Section 312 (Tier II) Ratings:**

| | |
|---|---|
| Immediate (acute) | Yes |
| Fire | No |
| Sudden Release | No |
| Reactivity | No |
| Delayed (chronic) | No |

**15.1.4.3 Section 313 (FORM R):** Not applicable

**15.1.5 RCRA**: Not applicable

**15.1.6 CAA** (Hazardous Air Pollutant/HAP): Not applicable

### 15.2 International Regulations:

**15.2.1 Canada:**

**15.2.1.1 WHMIS:** Not determined

**15.2.1.2 DSL/NDSL:** Listed in NDSL, Record No. 28636

### 15.3 State Regulations:

**CA Proposition 65:** No

## Section 16: OTHER INFORMATION

**REVISIONS:** This SDS was reformatted to comply with the new Hazard Communication Standard dated March 26, 2012, by the Regulatory Affairs Department of Tessenderlo Kerley, Inc. 7/1/2014.

Revised multiple sections for formatting and wording. 3/19/15.

*The information above is believed to be accurate and represents the best information currently available to Tessenderlo Kerley, Inc.(TKI). No warranty of merchantability, fitness for any particular purpose, or any other warranty is expressed or is to be implied regarding the accuracy or completeness of this information, the results to be obtained from the use of this information or the product, the safety of this product, or the hazards related to its use. Users should make their own investigations to determine the suitability of the information for their particular purpose and on the condition that they assume the risk of their use thereof. TKI reserves the right to revise this Safety Data Sheet periodically as new information becomes available.*

# SAFETY DATA SHEET
# EHC® Liquid Reagent Mix

**SDS # :** EHCLM-C
**Revision date:** 2016-02-03
**Format:** NA
**Version** 1.01

## 1. PRODUCT AND COMPANY IDENTIFICATION

**Product Identifier**

**Product Name** EHC® Liquid Reagent Mix

**Other means of identification**

**Alternate Commercial Name** EHC®-L Mix; EHC® Liquid - Solid Component

**Recommended use of the chemical and restrictions on use**

**Recommended Use:** Bioremediation product for the remediation of contaminated soil and groundwater

**Restrictions on Use:** Not for drinking water purification treatment.

**Manufacturer/Supplier**

PeroxyChem LLC
2005 Market Street
Suite 3200
Philadelphia, PA 19103
Phone: +1 267/ 422-2400 (General Information)
E-Mail: sdsinfo@peroxychem.com

**Emergency telephone number**

For leak, fire, spill or accident emergencies, call:
1 800 / 424 9300 (CHEMTREC - U.S.A.)
1 703 / 527 3887 (CHEMTREC - Collect - All Other Countries)
1 303/ 389-1409 (Medical - U.S. - Call Collect)

## 2. HAZARDS IDENTIFICATION

**Classification**

**OSHA Regulatory Status**

This chemical is considered hazardous by the 2012 OSHA Hazard Communication Standard (29 CFR 1910.1200).

Combustible dust

**GHS Label elements, including precautionary statements**

**EMERGENCY OVERVIEW**

**Warning**

**Hazard Statements**
May form combustible dust concentrations in air

**Precautionary Statements - Prevention**
Keep away from all ignition sources including heat,sparks and flame.
Keep container closed and grounded.
Prevent dust accumulations to minimize explosion hazard.

**Hazards not otherwise classified (HNOC)**
No hazards not otherwise classified were identified.

**Other Information**

CONTAINMENT HAZARD: Any vessel that contains wet EHC must be vented due to potential pressure build up from fermentation gases

## 3. COMPOSITION/INFORMATION ON INGREDIENTS

| Chemical name | CAS-No | Weight % |
|---|---|---|
| Iron salt | Proprietary | 92-97 |
| amino acid | Proprietary | 3-7 |

Occupational exposure limits, if available, are listed in section 8

## 4. FIRST AID MEASURES

**Eye Contact** Rinse thoroughly with plenty of water for at least 15 minutes, lifting lower and upper eyelids intermittently. Consult a physician.

**Skin Contact** Wash off with warm water and soap. Get medical attention if irritation develops and persists.

**Inhalation** Remove from exposure, lie down. If symptoms persist, call a physician.

**Ingestion** If swallowed, do not induce vomiting - seek medical advice.

**Protection of first-aiders** No information available.

**Most important symptoms and effects, both acute and delayed** Gastrointestinal effects. Inhalation of dust in high concentration may cause irritation of respiratory system.

**Indication of immediate medical attention and special treatment needed, if necessary** Treat symptomatically

## 5. FIRE-FIGHTING MEASURES

**Suitable Extinguishing Media** Use extinguishing measures that are appropriate to local circumstances and the surrounding environment.

**Specific Hazards Arising from the Chemical** Avoid generating dust; fine dust dispersed in air in sufficient concentrations, and in the presence of an ignition source is a potential dust explosion hazard.

**Hazardous Combustion Products** Carbon oxides (COx).

**Explosion data**
**Sensitivity to Mechanical Impact** Not sensitive.
**Sensitivity to Static Discharge** Not sensitive.

**Protective equipment and precautions for firefighters** As in any fire, wear self-contained breathing apparatus pressure-demand, MSHA/NIOSH (approved or equivalent) and full protective gear.

## 6. ACCIDENTAL RELEASE MEASURES

**Personal Precautions** For personal protection see Section 8. Avoid dispersal of dust in the air (i.e., cleaning dust surfaces with compressed air.).

**Other** Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). Use only non-sparking tools.

**Environmental Precautions** No special environmental precautions required.

**Methods for Containment** Sweep or vacuum up spillage and return to container. Avoid wetting dust and clean up as a dry powder with appropriate PPE for handling dry dusty materials; store in containers that keep material dry, segregated but allow to vent. Avoid dispersal of dust in the air (i.e., cleaning dust surfaces with compressed air.). Dust deposits should not be allowed to accumulate on surfaces, as these may form an explosive mixture if they are released into the atmosphere in sufficient concentration. Material may be recycled when contamination is not a problem.

**Methods for cleaning up** Following product recovery, flush area with water.

## 7. HANDLING AND STORAGE

**Handling** Avoid contact with skin, eyes and clothing. Do not ingest. Ensure adequate ventilation. Minimize dust generation and accumulation. Routine housekeeping should be instituted to ensure that dusts do not accumulate on surfaces. Dry powdered material can build static electricity when subjected to the friction of transfer and mixing operations. Provide adequate precautions, such as electrical grounding and bonding, or inert atmosphere.

**Storage** Keep tightly closed in a dry and cool place. Keep away from open flames, hot surfaces and sources of ignition.

**Incompatible products** . Strong oxidizing agents

## 8. EXPOSURE CONTROLS/PERSONAL PROTECTION

**Control parameters**

**Exposure Guidelines** Ingredients with workplace control parameters.

| Chemical name | ACGIH TLV | OSHA PEL | NIOSH | Mexico |
|---|---|---|---|---|
| Iron salt | TWA: 1 mg/m$^3$ | - | - | - |

| Chemical name | British Columbia | Quebec | Ontario TWAEV | Alberta |
|---|---|---|---|---|
| Iron salt | TWA: 1 mg/m$^3$ | TWA: 1.0 mg/m$^3$ | TWA: 1 mg/m$^3$ | TWA: 1 mg/m$^3$ |

**Appropriate engineering controls**

**Engineering measures** Ensure adequate ventilation, especially in confined areas. It is recommended that all dust control equipment such as local exhaust ventilation and material transport systems involved in the handling of this product contain explosion relief vents or an explosion suppression or an oxygen-deficient environment. Ensure that dust-handling systems (such as exhaust ducts, dust collectors, vessels, and processing equipment) are designed in a manner to prevent the escape of dust into the work area (i.e., there is no leakage from the equipment). Use only appropriately classified electrical equipment and powered industrial trucks.

**Individual protection measures, such as personal protective equipment**

| | |
|---|---|
| **Eye/Face Protection** | Safety glasses with side-shields. |
| **Skin and Body Protection** | Wear suitable protective clothing. |
| **Hand Protection** | Protective gloves |
| **Respiratory Protection** | When workers are facing concentrations above the exposure limit they must use appropriate certified respirators. |
| **Hygiene measures** | Handle in accordance with good industrial hygiene and safety practice. |

## 9. PHYSICAL AND CHEMICAL PROPERTIES

**Information on basic physical and chemical properties**

| | |
|---|---|
| **Appearance** | Dry powder |
| **Physical State** | Solid |
| **Color** | light gray |
| **Odor** | Slight |
| **Odor threshold** | No information available |
| **pH** | 4.5 (1% solution) |
| **Melting point/freezing point** | 100 °C |
| **Boiling Point/Range** | No information available |
| **Flash point** | Not applicable |
| **Evaporation Rate** | No information available |
| **Flammability (solid, gas)** | May be combustible at high temperatures |
| **Flammability Limit in Air** | |
| **Upper flammability limit:** | No information available |
| **Lower flammability limit:** | No information available |
| **Vapor pressure** | No information available |
| **Vapor density** | No information available |
| **Density** | No information available |
| **Specific gravity** | No information available |
| **Water solubility** | Fairly soluble |
| **Solubility in other solvents** | |
| **Partition coefficient** | No information available |
| **Autoignition temperature** | |
| **Decomposition temperature** | No information available |
| **Viscosity, kinematic** | No information available |
| **Viscosity, dynamic** | No information available |
| **Explosive properties** | Low level dust explosion hazard |
| **$K_{st}$** | 76 bar-m/sec: St1 Class dust |
| **Oxidizing properties** | No information available |
| **Molecular weight** | No information available |
| **Bulk density** | Not applicable |

## 10. STABILITY AND REACTIVITY

None under normal use conditions

| | |
|---|---|
| **Chemical Stability** | Stable under recommended storage conditions. Decomposes on heating. |
| **Possibility of Hazardous Reactions** | None under normal processing. |
| **Hazardous polymerization** | Hazardous polymerization does not occur. |
| **Conditions to avoid** | To avoid thermal decomposition, do not overheat. |
| **Incompatible materials** | Strong oxidizing agents. |
| **Hazardous Decomposition Products** | Carbon oxides (COx). |

## 11. TOXICOLOGICAL INFORMATION

**Product Information**

| | |
|---|---|
| **LD50 Oral** | Iron Salt: 2100 mg/kg (guinea pig)<br>Cysteine: 1890 mg/kg (rat) |
| **LD50 Dermal** | No information available |
| **LC50 Inhalation** | No information available |

**Sensitization** Not expected to be sensitizing based on the components.

**Information on toxicological effects**

**Symptoms** Dust is irritating eyes, nose, throat, and lungs.

**Delayed and immediate effects as well as chronic effects from short and long-term exposure**

**Carcinogenicity** Contains no ingredient listed as a carcinogen.

**Mutagenicity** This product is not recognized as mutagenic by Research Agencies

**Reproductive toxicity** This product does not contain any known or suspected reproductive hazards.

| | |
|---|---|
| **STOT - single exposure** | No information available. |
| **STOT - repeated exposure** | No information available. |

**Aspiration hazard** Not applicable.

## 12. ECOLOGICAL INFORMATION

**Ecotoxicity**

**Ecotoxicity effects** Not expected to have significant environmental effects

**Persistence and degradability** No information available.

**Bioaccumulation** No information available.

**Mobility** No information available.

**Other Adverse Effects** None known.

## 13. DISPOSAL CONSIDERATIONS

**Waste disposal methods** It must undergo special treatment, e.g. at suitable disposal site, to comply with local regulations.

**Contaminated Packaging** Dispose of in accordance with local regulations.

## 14. TRANSPORT INFORMATION

**DOT** NOT REGULATED

## 15. REGULATORY INFORMATION

## U.S. Federal Regulations

**SARA 313**
Section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986 (SARA). This product does not contain any chemicals which are subject to the reporting requirements of the Act and Title 40 of the Code of Federal Regulations, Part 372

**SARA 311/312 Hazard Categories**

| | |
|---|---|
| **Acute health hazard** | No |
| **Chronic health hazard** | No |
| **Fire hazard** | No |
| **Sudden release of pressure hazard** | No |
| **Reactive Hazard** | No |

**Clean Water Act**
This product does not contain any substances regulated as pollutants pursuant to the Clean Water Act (40 CFR 122.21 and 40 CFR 122.42)

**CERCLA/EPCRA**
This material, as supplied, does not contain any substances regulated as hazardous substances under the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) (40 CFR 302) or the Superfund Amendments and Reauthorization Act (SARA) (40 CFR 355). There may be specific reporting requirements at the local, regional, or state level pertaining to releases of this material

### International Inventories

| Component | TSCA (United States) | DSL (Canada) | EINECS/ELINCS (Europe) | ENCS (Japan) | China (IECSC) | KECL (Korea) | PICCS (Philippines) | AICS (Australia) | NZIoC (New Zealand) |

## SECTION 1: PRODUCT AND COMPANY IDENTIFICATION

**PRODUCT NAME:** Emulsified Zero Valent Iron (antimethanogenic)
**SYNONYMS:** EZVI /EZVI-CH4™
**PRODUCT CODES:**

**MANUFACTURER:** Provectus Environmental Products, Inc
**ADDRESS:** 2871 W. Forest Road, #2
Freeport, IL 61032

**EMERGENCY PHONE:** (815) 650-2230
**CHEMTREC PHONE:** (800) 424-9300 (Domestic)
**OTHER CALLS:**
**FAX PHONE:**

**CHEMICAL NAME:** Emulsified Zero Valent Iron (EZVI/EZVI-CH4™)
**CHEMICAL FAMILY:**
**CHEMICAL FORMULA:**

**PRODUCT USE:** Soil & Groundwater Remediation (DNAPL contamination)
**PREPARED BY:** Provectus Environmental Products, Inc.
**SECTION 1 NOTES:**

## SECTION 2: COMPOSITION/INFORMATION ON INGREDIENTS

| INGREDIENT: | CAS NO. | % WT | % VOL | SARA 313 REPORTABLE |
|---|---|---|---|---|
| Iron (Fe) | 7439-89-6 | 5 – 20 | NA | NA |
| Sorbitan Trioleate | 26266-58-0 | 1 – 5 | NA | NA |
| Food Grade Veg Oil | 8001-22-7 | 30 – 40 | NA | NA |
| Potable Water | 7732-18-5 | 40 – 50 | NA | NA |
| Yeast Extracts* | 8013-01-2 | 0.5 – 5 | NA | NA |

**SECTION 2 NOTES:**

## SECTION 3: HAZARDS IDENTIFICATION

**EMERGENCY OVERVIEW:**

**ROUTES OF ENTRY:**

**EYES:** YES

**SKIN:** NO

**INGESTION:** YES

**INHALATION:** NO

**ACUTE HEALTH HAZARDS:** NONE KNOWN
**CHRONIC HEALTH HAZARDS:** NONE KNOWN
**MEDICAL CONDITIONS GENERALLY AGGRAVATED BY EXPOSURE:** NONE KNOWN
**CARCINOGENICITY**
**OSHA:** NA **ACGIH:** NA **NTP:** NA **IARC:** NA **OTHER:** NA

**SECTION 3 NOTES:**

## SECTION 4: FIRST AID MEASURES

**EYES: In case of eye contact, rinse opened eye for 15 minutes with water, then consult physician.**

**SKIN: In case of skin contact, immediately wash affected area(s) with soap & water and rinse thoroughly.**

**INGESTION: After swallowing seek immediate medical advice. Make physician aware that the following symptoms may occur; stomach cramps, nausea, gastric or intestinal disorders.**

**INHALATION: NA**

**NOTES TO PHYSICIANS OR FIRST AID PROVIDERS:**

**SECTION 4 NOTES:**

## SECTION 5: FIRE-FIGHTING MEASURES

**FLAMMABLE LIMITS IN AIR, UPPER: NA**
**(% BY VOLUME) LOWER: NA**

**FLASH POINT:**
**F: >482 ºF**
**C: >250 ºC**
**METHOD USED: Closed Cup**

**AUTOIGNITION TEMPERATURE:**
**F: >760 ºF**
**C: >404 ºC**

**NFPA HAZARD CLASSIFICATION**
**HEALTH: 1 FLAMMABILITY: 2 REACTIVITY: 1**
**OTHER:**

**HMIS HAZARD CLASSIFICATION**
**HEALTH: 1 FLAMMABILITY: 2 REACTIVITY: 1**
**PROTECTION:**

**EXTINGUISHING MEDIA: Extinguishing Powder**

**SPECIAL FIRE FIGHTING PROCEDURES: DO NOT use water, CO2, or halogenated extinguishers.**

**UNUSUAL FIRE AND EXPLOSION HAZARDS: NA**

**HAZARDOUS DECOMPOSITION PRODUCTS: NA**

**SECTION 5 NOTES:**

## SECTION 6: ACCIDENTAL RELEASE MEASURES

**ACCIDENTAL RELEASE MEASURES:**
**Personal Safety Measures: Wear protective equipment, keep unprotected persons away, ensure adequate ventilation**
**Environmental Safey Measures: NA**
**Spill/Cleanup Safety Measures: Dispose of collected waste and contaminated materials as directed in Section 7.**

**SECTION 6 NOTES:**

## SECTION 7: HANDLING AND STORAGE

**HANDLING AND STORAGE: Spilled material should be contained and recovered into drums**
**OTHER PRECAUTIONS: Store in cool, dry, ventilated area. Do Not store near halogens, oxidizers or acidic materials. Keep ignition sources away and ensure good ventilation.**

**SECTION 7 NOTES:**

## SECTION 8: EXPOSURE CONTROLS/PERSONAL PROTECTION

**ENGINEERING CONTROLS: Block off handling or spill area from unprotected persons**

**VENTILATION : Ensure area is adequately ventilated.**

**RESPIRATORY PROTECTION: NA**

**EYE PROTECTION: safety goggles/splash shield**

**SKIN PROTECTION: tyvec suit with rubberized gloves (neoprene)**

**OTHER PROTECTIVE CLOTHING OR EQUIPMENT: slip resistant footwear**

**WORK HYGIENIC PRACTICES: Surfaces covered with EZVI can become VERY slippery. Exercise additional care when handling/cleaning up to avoid slip and fall injury.**

**EXPOSURE GUIDELINES: NA**

**SECTION 8 NOTES:**

## SECTION 9: PHYSICAL AND CHEMICAL PROPERTIES

**APPEARANCE: Black/Dark Gray viscous material**
**ODOR: cooking oil odor**
**PHYSICAL STATE: liquid**

**pH AS SUPPLIED:**
**pH (Other):**

# Material Safety Data Sheet
## Ferrous sulfate MSDS

## Section 1: Chemical Product and Company Identification

**Product Name:** Ferrous sulfate

**Catalog Codes:** SLF1516

**CAS#:** 13463-43-9

**RTECS:** Not available.

**TSCA:** TSCA 8(b) inventory: No products were found.

**CI#:** Not available.

**Synonym:** Ferrous Sulfate Hydrate; Ferrous Sulfate Dried Powder

**Chemical Name:** Ferrous Sulfate

**Chemical Formula:** FeSO4.xH2O

**Contact Information:**

**Sciencelab.com, Inc.**
14025 Smith Rd.
Houston, Texas 77396

US Sales: **1-800-901-7247**
International Sales: **1-281-441-4400**

Order Online: ScienceLab.com

**CHEMTREC (24HR Emergency Telephone), call:** 1-800-424-9300

**International CHEMTREC, call:** 1-703-527-3887

**For non-emergency assistance, call:** 1-281-441-4400

## Section 2: Composition and Information on Ingredients

**Composition:**

| Name | CAS # | % by Weight |
|---|---|---|
| Ferrous sulfate | 13463-43-9 | 100 |

**Toxicological Data on Ingredients:** Ferrous sulfate LD50: Not available. LC50: Not available.

## Section 3: Hazards Identification

**Potential Acute Health Effects:** Hazardous in case of skin contact (irritant), of eye contact (irritant), of ingestion, of inhalation.

**Potential Chronic Health Effects:**
CARCINOGENIC EFFECTS: Not available. MUTAGENIC EFFECTS: Not available. TERATOGENIC EFFECTS: Not available. DEVELOPMENTAL TOXICITY: Not available. The substance may be toxic to kidneys, liver, cardiovascular system, central nervous system (CNS). Repeated or prolonged exposure to the substance can produce target organs damage.

## Section 4: First Aid Measures

**Eye Contact:**
Check for and remove any contact lenses. In case of contact, immediately flush eyes with plenty of water for at least 15 minutes. Cold water may be used. Get medical attention.

**Skin Contact:**
In case of contact, immediately flush skin with plenty of water. Cover the irritated skin with an emollient. Remove contaminated clothing and shoes. Cold water may be used.Wash clothing before reuse. Thoroughly clean shoes before reuse. Get medical attention.

**Serious Skin Contact:**
Wash with a disinfectant soap and cover the contaminated skin with an anti-bacterial cream. Seek medical attention.

**Inhalation:**
If inhaled, remove to fresh air. If not breathing, give artificial respiration. If breathing is difficult, give oxygen. Get medical attention.

**Serious Inhalation:** Not available.

**Ingestion:**
Do NOT induce vomiting unless directed to do so by medical personnel. Never give anything by mouth to an unconscious person. If large quantities of this material are swallowed, call a physician immediately. Loosen tight clothing such as a collar, tie, belt or waistband.

**Serious Ingestion:** Not available.

## Section 5: Fire and Explosion Data

**Flammability of the Product:** Non-flammable.

**Auto-Ignition Temperature:** Not applicable.

**Flash Points:** Not applicable.

**Flammable Limits:** Not applicable.

**Products of Combustion:** Not available.

**Fire Hazards in Presence of Various Substances:** Not applicable.

**Explosion Hazards in Presence of Various Substances:**
Risks of explosion of the product in presence of mechanical impact: Not available. Risks of explosion of the product in presence of static discharge: Not available.

**Fire Fighting Media and Instructions:** Not applicable.

**Special Remarks on Fire Hazards:** Not available.

**Special Remarks on Explosion Hazards:** Not available.

## Section 6: Accidental Release Measures

**Small Spill:**
Use appropriate tools to put the spilled solid in a convenient waste disposal container. Finish cleaning by spreading water on the contaminated surface and dispose of according to local and regional authority requirements.

**Large Spill:**
Use a shovel to put the material into a convenient waste disposal container. Finish cleaning by spreading water on the contaminated surface and allow to evacuate through the sanitary system. Be careful that the product is not present at a concentration level above TLV. Check TLV on the MSDS and with local authorities.

## Section 7: Handling and Storage

**Precautions:**
Do not breathe dust. Wear suitable protective clothing. In case of insufficient ventilation, wear suitable respiratory equipment. If you feel unwell, seek medical attention and show the label when possible. Avoid contact with skin and eyes.

**Storage:**
Hygroscopic. Keep container tightly closed. Keep container in a cool, well-ventilated area. Do not store above 24°C (75.2°F).

## Section 8: Exposure Controls/Personal Protection

**Engineering Controls:**
Use process enclosures, local exhaust ventilation, or other engineering controls to keep airborne levels below recommended exposure limits. If user operations generate dust, fume or mist, use ventilation to keep exposure to airborne contaminants below the exposure limit.

**Personal Protection:**
Splash goggles. Lab coat. Dust respirator. Be sure to use an approved/certified respirator or equivalent. Gloves.

**Personal Protection in Case of a Large Spill:**
Splash goggles. Full suit. Dust respirator. Boots. Gloves. A self contained breathing apparatus should be used to avoid inhalation of the product. Suggested protective clothing might not be sufficient; consult a specialist BEFORE handling this product.

**Exposure Limits:** Not available.

## Section 9: Physical and Chemical Properties

**Physical state and appearance:** Solid.

**Odor:** Not available.

**Taste:** Not available.

**Molecular Weight:** 151.9 g/mole + H20

**Color:** Grayish -white to yellowish. (Light.)

**pH (1% soln/water):** Not available.

**Boiling Point:** Not available.

**Melting Point:** Not available.

**Critical Temperature:** Not available.

**Specific Gravity:** Not available.

**Vapor Pressure:** Not applicable.

**Vapor Density:** Not available.

**Volatility:** Not available.

**Odor Threshold:** Not available.

**Water/Oil Dist. Coeff.:** Not available.

**Ionicity (in Water):** Not available.

**Dispersion Properties:** See solubility in water.

**Solubility:** Soluble in cold water.

## Section 10: Stability and Reactivity Data

**Stability:** The product is stable.

**Instability Temperature:** Not available.

**Conditions of Instability:** Incompatibles

**Incompatibility with various substances:** Not available.

**Corrosivity:** Not available.

**Special Remarks on Reactivity:**
Hygroscopic. Loses water at about 300 C. No other information found.

**Special Remarks on Corrosivity:** Not available.

**Polymerization:** Will not occur.

## Section 11: Toxicological Information

**Routes of Entry:** Inhalation. Ingestion.

**Toxicity to Animals:**
LD50: Not available. LC50: Not available.

**Chronic Effects on Humans:** May cause damage to the following organs: kidneys, liver, cardiovascular system, central nervous system (CNS).

**Other Toxic Effects on Humans:** Hazardous in case of skin contact (irritant), of ingestion, of inhalation.

**Special Remarks on Toxicity to Animals:** Not available.

**Special Remarks on Chronic Effects on Humans:** May affect genetic material (mutagenic)

**Special Remarks on other Toxic Effects on Humans:**
Acute Potential Health Effects: Skin: May cause skin irritation. Eyes: May cause eye irritation. Inhalation: May cause respiratory tract irritation. Ingestion: Harmful if swallowed. May cause gastrointestinal tract distrubances and irritation with nausea, vomiting, colic, constipation, diarrhea, black stool. May also affect behavior/Central Nervous System (somnolence -general depressed activity), respiration, cardiovascular system, liver, kidneys (pink urine discoloration). Chronic Potential Health Effects: Repeated exposure via ingestion may increase iron levels in the liver, and spleen. Damage may occur to spleen and liver.

## Section 12: Ecological Information

**Ecotoxicity:** Not available.

**BOD5 and COD:** Not available.

**Products of Biodegradation:**
Possibly hazardous short term degradation products are not likely. However, long term degradation products may arise.

**Toxicity of the Products of Biodegradation:** The product itself and its products of degradation are not toxic.

**Special Remarks on the Products of Biodegradation:** Not available.

## Section 13: Disposal Considerations

**Waste Disposal:**
Waste must be disposed of in accordance with federal, state and local environmental control regulations.

## Section 14: Transport Information

**DOT Classification:** Not a DOT controlled material (United States).

**Identification:** Not applicable.

**Special Provisions for Transport:** Not applicable.

## Section 15: Other Regulatory Information

**Federal and State Regulations:** No products were found.

**Other Regulations:** OSHA: Hazardous by definition of Hazard Communication Standard (29 CFR 1910.1200).

**Other Classifications:**

**WHMIS (Canada):** Not controlled under WHMIS (Canada).

**DSCL (EEC):**
R36/38- Irritating to eyes and skin. S2- Keep out of the reach of children. S46- If swallowed, seek medical advice immediately and show this container or label.

**HMIS (U.S.A.):**

**Health Hazard:** 2

**Fire Hazard:** 0

**Reactivity:** 0

**Personal Protection:** E

**National Fire Protection Association (U.S.A.):**

**Health:** 2

**Flammability:** 0

**Reactivity:** 0

**Specific hazard:**

**Protective Equipment:**
Gloves. Lab coat. Dust respirator. Be sure to use an approved/certified respirator or equivalent. Splash goggles.

## Section 16: Other Information

**References:** Not available.

**Other Special Considerations:** Not available.

**Created:** 10/09/2005 05:33 PM

**Last Updated:** 05/21/2013 12:00 PM

# MINERAL MASTERS

130 W GRAND LAKE BLVD., WEST CHICAGO, IL 60185

FOR CHEMICAL EMERGENCY. SPILL, LEAK, EXPOSURE, OR ACCIDENT, CALL CHEMTREC, 1-800-424-9300

## MATERIAL SAFETY DATA SHEET

**Revised 8-11-10**

### 1. IDENTIFICATION OF THE PRODUCT

**MM-2480**

### 2. HAZARDS IDENTIFICATION

Appearance and Odor

Form : Granular solid
Color : White
Odor : None

Emergency Overview :
Aqueous solutions or powders that become wet render surfaces extremely slippery.

### 3. COMPOSITION/INFORMATION ON INGREDIENTS

Identification : Cationic water-soluble polymer.

Regulated Components
None.

### 4. FIRST AID MEASURES

Inhalation : No hazards which require special first aid measures.
Skin contact : No hazards which require special first aid measures. Wash with water and soap as a precaution. Call a physician if irritation persists.

Eye contact : Rinse thoroughly with plenty of water, also under the eyelids. In case of persistent eye irritation, consult a physician.

Ingestion : No hazards which require special first aid measures. The product is not considered toxic based on studies on laboratory animals.

### 5. FIRE-FIGHTING MEASURES

Suitable extinguishing media : Water. Water spray. Foam. Carbon dioxide (CO2). Dry powder.

Precautions : Aqueous solutions or powders that become wet render surfaces extremely slippery.

Special protective equipment for firefighters : No special protective equipment required.

Flash point : Not applicable
Autoignition temperature : Not applicable

### 6. ACCIDENTAL RELEASE MEASURES

Personal precautions : No special precautions required.

Environmental precautions : As with all chemical products, do not flush into surface water.

Methods for cleaning up : Do not flush with water Clean up promptly by sweeping or vacuum. Keep in suitable and closed containers for disposal. After cleaning, flush away traces with water.

### 7. HANDLING AND STORAGE

Handling
Safe handling advice : Avoid contact with skin and eyes. Avoid dust formation. Do not breathe dust. Wash hands before breaks and at the end of workday.

Storage

Keep in a dry, cool place (0 - 35 °C).

### 8. EXPOSURE CONTROLS / PERSONAL PROTECTION

Engineering measures
Use local exhaust if dusting occurs. Natural ventilation is adequate in absence of dusts.

Personal protective equipment
Respiratory protection : Dust safety masks are recommended where concentration of total dust is more than 10 mg/m3.

Hand protection : Rubber gloves.

Eye protection : Safety glasses with side-shields. Do not wear contact lenses where this product is used.

Skin and body protection : Chemical resistant apron or protective suit if spashing or repeated contact with solution is likely.

Hygiene measures
Wash hands before breaks and at the end of workday. Handle in accordance with good industrial hygiene and safety practice.

### 9. PHYSICAL AND CHEMICAL PROPERTIES

Form : Granular solid
Color : White Odor : None

pH : 2.5 - 4.5 @ 5 g/l

Melting point/range : Not applicable Flash point : Not applicable

Autoignition temperature : Not applicable

Approx. bulk density : 0.62 Water solubility : See Technical Bulletin

LogPow : 0

### 10. STABILITY AND REACTIVITY

Stability : Stable. Hazardous polymerisation does not occur.

Materials to avoid : Oxidizing agents may cause exothermic reactions.

Hazardous decomposition products : Burning of the dried material can produce: hydrogen chloride gas, nitrogen oxides (NOx), carbon oxides.

### 11. TOXICOLOGICAL INFORMATION

Acute toxicity

Skin : The results of testing on rabbits showed this material to be non-toxic even at high dose levels.

Oral : LD50/oral/rat = 5000 mg/kg.

Inhalation : The product is not expected to be toxic by inhalation.

Irritation

Skin : The results of testing on rabbits showed this material to be non-irritating to the skin.

Eyes : Testing conducted according to the Draize technique showed the material produces no corneal or iridial effects and only slight transitory conjuctival effects similar to those which all granular materials have on conjuctivae.

Sensitization : The results of testing on guinea pigs showed this material to be non-sensitizing.

Chronic toxicity : A one-year feeding study on rats did not reveal adverse health effects. A one-year feeding study on dogs did not reveal adverse health effects.

### 12. ECOLOGICAL INFORMATION

Aquatic toxicity

Toxicity to fish (dano rerio, rainbow trout, fathead minnow): LC50/96 hours = 5 - 10 mg/L.

Toxicity to daphnia : EC50/48 hours = 20 - 50 mg/L.

Toxicity to algae : Algal inhibition tests are not appropriate. The flocculation characteristics of the product interfere directly in the test medium preventing homogenous distribution which invalidates the test.

*Environmental fate*

*Hydrolysis : At natural pHs (>6) the polymer degrades due to hydrolysis to more than 70% in 28 days. The hydrolysis products are not harmfull to aquatic organisms.*

*LogPow : 0*

*Bioaccumulation : Does not bioaccumulate.*

*Other ecological information :*
*The effects of this product on aquatic organisms are rapidly and significantly mitigated by the presence of dissolved organic carbon in the aquatic environment.*

## *13. DISPOSAL CONSIDERATIONS*

*Disposal : In accordance with local, state and federal regulations.*

*Container : Rinse empty containers with water and use the rinse water to prepare the working solution. Can be landfilled or incinerated, when in compliance with local, state and federal regulations.*

## *14. TRANSPORT INFORMATION*

*DOT*

*Remarks : Not classified as dangerous in the meaning of DOT regulations.*

*IMDG/IMO*
*Remarks : Not classified as dangerous in the meaning of IMO/IMDG regulations.*
*ICAO/IATA*
*Remarks : Not classified as dangerous in the meaning of ICAO/IATA regulations.*

## *15. REGULATORY INFORMATION*

*US SARA Reporting Requirements*

*SARA Title III Sections*
*Sara (311, 312) hazard class : Not concerned*

*State Regulations*

*The following statement is made in order to comply with the California Safe Drinking Water and Toxic Enforcement Act of 1986. This product contains the following substance (s) known to the State of California to cause cancer : Acrylamide.*

*International Inventories*

*European Union (EINECS/ELINCS) : All components of this product are either listed on the inventory or are exempt from listing.*

*USA (TSCA) : All components of this product are either listed on the inventory or are exempt from listing.*

*Canada (DSL) : All components of this product are either listed on the inventory or are exempt from listing.*

*Australia (AICS) : All components of this product are either listed on the inventory or are exempt from listing.*

*China (IECSC) : All components of this product are either listed on the inventory or are exempt from listing.*

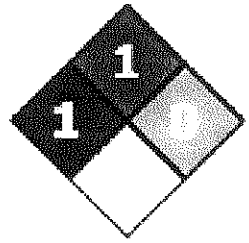
*Japan (ENCS) : All components of this product are either listed on the inventory or are exempt from listing.*

*Korea (ECL) : All components of this product are either listed on the inventory or are exempt from listing.*

*Philippines (PICCS) : All components of this product are either listed on the inventory or are exempt from listing.*

## *16. OTHER INFORMATION*

*NFPA and HMIS Ratings :*



*NFPA :*

*Health : 1*
*Flammability : 1*
*Instability : 0*

*HMIS :*

*Health : 1*
*Flammability : 1*
*Physical Hazard : 0*

***PREPARED BY MINERAL MASTERS THIS INFORMATION IS OFFERED IN GOOD FAITH AS TYPICAL VALUES AND NOT AS A PRODUCT SPECIFICATION. NO WARRANTY, EXPRESSED OR IMPLIED IS HEREBY MADE. THE RECOMMENDED INDUSTRIAL HYGIENE AND SAFE HANDLING PROCEDURES ARE BELIEVED TO BE GENERALLY APPLICABLE. HOWEVER,E ACH USER SHOULD REVIEW THESE RECOMMENDATIONS IN THE SPECIFIC CONTEXT OF THE INTENDED USE AND DETERMINE WHETHER THEY ARE APPROPRIATE.***

**MATERIAL SAFETY DATA SHEET**
**MOLASSES/MOLASSES BLENDS/BINDERS**

## 1. CHEMICAL PRODUCT AND COMPANY IDENTIFICATION

| Chemical Name | Chemical Formula | Molecular Weight |
|---|---|---|
| N/A | Mixture of liquid Agricultural commodities | No data |

Trade Name – Molasses/Molasses Blends

Synonyms: DOT Identification No.

Liquid animal supplement: N/A

Company Identification:
Westway Trading Corporation
365 Canal Street, Suite 2900
New Orleans, Louisiana 70130
(504) 525-9741

## 2. COMPOSITION, INFORMATION ON INGREDIENTS

| Component(s), Chemical Name | CAS Registry No. | %(Approx.) | ACGIH TLV-TWA |
|---|---|---|---|
| Proprietary **See ingredient tag** | NA | No data | No data |

## 3. HAZARDS IDENTIFICATION

Emergency Overview

This material should be stored in a vented tank designed to contain a material with a specific gravity of 1.3 or greater. Material can ferment if excessive moisture contamination is allowed. Fermentation can yield carbon dioxide with possible traces of ethanol or volatile fatty acids (e.g. acetic, propionic, lactic, or butyric) and if exposed to a spark or flame may result in an explosion. These conditions should be avoided. If maintenance of tank requires entry by personnel, OSHA's Confined Space standard (29CFR1910.146) shall be complied with. If welding is to be performed, the tank should be gas freed and only certified welders shall perform welding operations.

Potential Health Effects

Eyes - Mild irritant

Skin - None

Inhalation – Insufficient oxygen may be present in vessels containing the product due to the generation of carbon monoxide during fermentation

## 4. FIRST AID MEASURES

Eyes: Flush eyes for 15 minutes.

Skin: Wash with soap and water.

Ingestion: No data

## 5. FIRE FIGHTING MEASURES

| Flashpoint (Method used) | Flammable Limits in Air |
|---|---|
| Non-flammable<br>Non-combustible | Non-flammable<br>Non-combustible |

Extinguishing Agents - NA

Unusual Fire and Explosion Hazards – Fermentation occurs when diluted with water and is accelerated by heat. During fermentation, carbon monoxide with possible traces of ethanol or volatile fatty acids (e.g., acetic, propionic, lactic, or butyric) is given off, which produces inhalation hazards and possible explosion hazards.

## 6. ACCIDENTAL RELEASE MEASURES

Steps to be Taken in Case Material is Released or Spilled

Small spills - Stop the source of the spill. Recover as much product as possible for reuse. Absorb remaining spill and dispose solids in waste container.

Large spills - Stop the source of the spill. Create diversionary structures to minimize the extent of the release. Prevent the release from entering a waterway or sewer. Recover useable product. Absorb remaining spill and dispose of at an approved facility such as a municipal landfill or land application site.

## 7. HANDLING AND STORAGE

This material should be stored in a vented tank designed to contain a material with a specific gravity of 1.3 or greater. Material can ferment if excessive moisture contamination is allowed.

## 8. EXPOSURE CONTROLS, PERSONAL PROTECTION

Respiratory Protection - None

Ventilation – Provide adequate ventilation to prevent accumulation of vapors.

Skin Protection - Rubber gloves

Eye Protection - Safety glasses

Hygiene - Wash any exposed area promptly with soap and water. Launder contaminated clothing.

Other Control Measures - None

## 9. PHYSICAL AND CHEMICAL PROPERTIES

| | |
|---|---|
| Appearance<br>Dark brown syrupy liquid | Odor<br>Sweet |
| Physical State<br>Liquid | Specific Gravity<br>1.45 |
| Boiling Point<br>Very high | Freezing/Melting Point<br>Varies |
| Vapor Pressure<br>Low | % Volatile, by Volume<br>No data |
| Evaporation Rate<br>No data | Vapor Density in Air<br>Water vapor only |
| Solubility in Water<br>Soluble | pH<br>2.25 to 6.0 |

## 10. STABILITY AND REACTIVITY

Chemical Stability - Stable

Conditions to Avoid – Excess moisture or heat. Unventilated containers.

Incompatibility with Other Materials - Reacts with concentrated nitric acid or concentrated Sulphuric acid. Ferments when diluted with water.

Hazard Decomposition Products – Carbon monoxide, alcohol or fatty acid vapors

Hazardous Polymerization - NA

## 11. ECOLOGICAL INFORMATION

Prevent releases to land or water. Results in high Biological Oxygen Demand (BOD) and potential oxygen depletion of aquatic systems.

## 12. DISPOSAL CONSIDERATIONS

Dispose of waste material at an approved municipal landfill or land application site.

## 13. TRANSPORT INFORMATION

Hazardous Materials Description/ Proper Shipping Name - NA

DOT Hazard Class - NA

DOT Identification Number - NA

X  This product is not a DOT hazardous material.

## 14. REGULATORY INFORMATION

Discharges to a water of the U.S. are regulated by the Environmental Protection Agency.

## 15. OTHER INFORMATION

None.

Date of Preparation: 3/15/96 **REVISED: 10/12/01**

1 – The precise composition of this product is proprietary information. A more complete disclosure will be provided to a physician in the event of a medical emergency.

2 – The soluble substrates and emulsifiers are generally recognized as safe for food contact.

| Section 4: First-Aid Measures | |
|---|---|
| **Routes of Exposure** | **Emergency First-Aid Procedures** |
| Inhalation | Remove to fresh air. |
| Eye Contact | Flush with water for 15 minutes; if irritation persists see a physician. |
| Skin Contact | Wash with mild soap and water. |
| Ingestion | Product is non-toxic. If nausea occurs, induce vomiting and seek medical attention. |

| Section 5: Fire-Fighting Measures | |
|---|---|
| Extinguishing Media: | $CO_2$, foam, dry chemical<br>Note: Water, fog and foam may cause frothing and spattering. |
| Special Fire Fighting Procedures: | Wear self-contained breathing apparatus and chemical resistant clothing. Use water spray to cool fire exposed containers. |
| Fire Hazard(s): | Burning will cause oxides of carbon. |

| Section 6: Accidental Release Measures | |
|---|---|
| Personal Precautions: | Avoid contact with eyes and skin. Do not consume. |
| Emergency Procedures: | N/A |
| Methods & Materials used for Containment: | Compatible granular absorbent |
| Cleanup Procedures: | Spread compatible granular absorbent over spill area and sweep using broom and pan; dispose in appropriate receptacle. Clean area with water. |

| Section 7: Handling and Storage | |
|---|---|
| Safe Handling & Storage: | Do not store near excessive heat or oxidizers. |
| Other Precautions: | Consumption of food and beverages should be prevented in work area where product is being used. After handling product, always wash hands and face thoroughly with soap and water before eating, drinking, or smoking. |

| Section 8: Exposure Controls/Personal Protection | | |
|---|---|---|
| **Exposure Limits** | | |
| OSHA PEL: | NE | |
| ACGIH TLV: | NE | |
| NIOSH REL: | NE | |
| **Personal Protective Measures** | | |
| Respiratory Protection: | Not normally required. P95 respirator if aerosols might be generated. | |
| Hand Protection: | Protective gloves are recommended | |
| Eye Protection: | Recommended | |
| Engineering Measures: | Local exhaust ventilation if aerosols are generated | |
| Hygiene Measures: | Wash promptly with soap & water if skin becomes irritated from contact. | |
| Other Protection: | Wear appropriate clothing to prevent skin contact. | |

| | IARC: | No |
| | OSHA: | No |

| Section 12: Ecological Information (non-mandatory) |
|---|
| There is no data on the ecotoxicity of this product. |

| Section 13: Disposal Considerations (non-mandatory) | |
|---|---|
| Waste Disposal Methods: | Dispose of according to Federal and local regulations for non-hazardous waste. Recycle, if practical. |

| Section 14: Transport Information (non-mandatory) |
|---|
| The product is not covered by international regulation on the transport of dangerous goods. |
| No transport warning required. |

| Section 15: Regulatory Information (non-mandatory) |
|---|
| N/A |

| Section 16: Other Information | |
|---|---|
| Date of Preparation: | 29 May 2014 |
| Last Modified Date: | 5 September 2014 |
| The information contained herein is based on available data and is believed to be correct. However, EOS Remediation, LLC makes no warranty, expressed or implied, regarding the accuracy of this data or the results to be obtained thereof. This information and product are furnished on the condition that the person receiving them shall make his/her own determination as to the suitability of the product for his/her particular purpose. | |

# Sodium Hydroxide, 50% w/w

Safety Data Sheet

according to Federal Register / Vol. 77, No. 58 / Monday, March 26, 2012 / Rules and Regulations

Date of issue: 10/16/2013 Revision date: 02/07/2017 Supersedes: 10/16/2013 Version: 1.1

## SECTION 1: Identification

### 1.1. Identification

| | | |
|---|---|---|
| Product form | : | Mixtures |
| Product name | : | Sodium Hydroxide, 50% w/w |
| CAS No | : | 1310-73-2 |
| Product code | : | LC24150 |
| Formula | : | NaOH |
| Synonyms | : | caustic soda 50% W/W / soda lye, 50%, aqueous solution / white caustic, 50%, aqueous solution |

### 1.2. Relevant identified uses of the substance or mixture and uses advised against

| | | |
|---|---|---|
| Use of the substance/mixture | : | Industrial use |
| Recommended use | : | Laboratory chemicals |
| Restrictions on use | : | Not for food, drug or household use |

### 1.3. Details of the supplier of the safety data sheet

LabChem Inc
Jackson's Pointe Commerce Park Building 1000, 1010 Jackson's Pointe Court
Zelienople, PA 16063 - USA
T 412-826-5230 - F 724-473-0647
info@labchem.com - www.labchem.com

### 1.4. Emergency telephone number

| | | |
|---|---|---|
| Emergency number | : | CHEMTREC: 1-800-424-9300 or 011-703-527-3887 |

## SECTION 2: Hazard(s) identification

### 2.1. Classification of the substance or mixture

**GHS-US classification**

| | |
|---|---|
| Skin corrosion/irritation, Category 1B | H314 |
| Serious eye damage/eye irritation, Category 1 | H318 |
| Hazardous to the aquatic environment — Acute Hazard, Category 3 | H402 |

Full text of H statements : see section 16

### 2.2. Label elements

**GHS-US labelling**

Hazard pictograms (GHS-US) :

GHS05

Signal word (GHS-US) : Danger

Hazard statements (GHS-US) :
H314 - Causes severe skin burns and eye damage
H402 - Harmful to aquatic life

Precautionary statements (GHS-US) :
P260 - Do not breathe mist, vapours, spray
P264 - Wash exposed skin thoroughly after handling
P273 - Avoid release to the environment
P280 - Wear protective gloves, protective clothing, eye protection, face protection
P301+P330+P331 - IF SWALLOWED: rinse mouth. Do NOT induce vomiting
P303+P361+P353 - IF ON SKIN (or hair): Remove/Take off immediately all contaminated clothing. Rinse skin with water/shower
P305+P351+P338 - If in eyes: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing
P310 - Immediately call a POISON CENTER or doctor/physician
P363 - Wash contaminated clothing before reuse
P405 - Store locked up
P501 - Dispose of contents/container to comply with local, state and federal regulations
If inhaled: Remove person to fresh air and keep comfortable for breathing

### 2.3. Other hazards

No additional information available

### 2.4. Unknown acute toxicity (GHS US)

Not applicable

## SECTION 3: Composition/information on ingredients

### 3.1. Substances

Not applicable

### 3.2. Mixtures

| Name | Product identifier | % | GHS-US classification |
|---|---|---|---|
| Sodium Hydroxide | (CAS No) 1310-73-2 | 50 | Acute Tox. 4 (Dermal), H312<br>Skin Corr. 1A, H314<br>Eye Dam. 1, H318<br>Aquatic Acute 3, H402 |
| Water | (CAS No) 7732-18-5 | 50 | Not classified |

Full text of hazard classes and H-statements : see section 16

## SECTION 4: First aid measures

### 4.1. Description of first aid measures

First-aid measures general : Check the vital functions. Unconscious: maintain adequate airway and respiration. Respiratory arrest: artificial respiration or oxygen. Cardiac arrest: perform resuscitation. Victim conscious with laboured breathing: half-seated. Victim in shock: on his back with legs slightly raised. Vomiting: prevent asphyxia/aspiration pneumonia. Prevent cooling by covering the victim (no warming up). Keep watching the victim. Give psychological aid. Keep the victim calm, avoid physical strain. Depending on the victim's condition: doctor/hospital. Never give anything by mouth to an unconscious person. If you feel unwell, seek medical advice (show the label where possible).

First-aid measures after inhalation : Remove the victim into fresh air. Respiratory problems: consult a doctor/medical service. Remove victim to fresh air and keep at rest in a position comfortable for breathing. Immediately call a POISON CENTER or doctor/physician.

First-aid measures after skin contact : Wash immediately with lots of water (15 minutes)/shower. Do not apply (chemical) neutralizing agents. Remove clothing while washing. Do not remove clothing if it sticks to the skin. Cover wounds with sterile bandage. Consult a doctor/medical service. If burned surface > 10%: take victim to hospital. Remove/Take off immediately all contaminated clothing. Rinse skin with water/shower. Immediately call a POISON CENTER or doctor/physician.

First-aid measures after eye contact : Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing. Immediately call a POISON CENTER or doctor/physician.

First-aid measures after ingestion : Rinse mouth with water. Immediately after ingestion: give lots of water to drink. Do not induce vomiting. Do not give activated charcoal. Do not give chemical antidote. Immediately consult a doctor/medical service. Call Poison Information Centre (www.big.be/antigif.htm). Take the container/vomit to the doctor/hospital. Ingestion of large quantities: immediately to hospital. Rinse mouth. Do NOT induce vomiting. Immediately call a POISON CENTER or doctor/physician.

### 4.2. Most important symptoms and effects, both acute and delayed

Symptoms/injuries : Causes severe skin burns and eye damage.

Symptoms/injuries after inhalation : EXPOSURE TO HIGH CONCENTRATIONS: Dry/sore throat. Coughing. Irritation of the respiratory tract. Irritation of the nasal mucous membranes. FOLLOWING SYMPTOMS MAY APPEAR LATER: Possible laryngeal spasm/oedema. Risk of lung oedema. Respiratory difficulties.

Symptoms/injuries after skin contact : Caustic burns/corrosion of the skin. Slow-healing wounds.

Symptoms/injuries after eye contact : Corrosion of the eye tissue. Permanent eye damage. Causes serious eye damage.

Symptoms/injuries after ingestion : Vomiting. Diarrhoea. Burns to the gastric/intestinal mucosa. Possible esophageal perforation. Bleeding of the gastrointestinal tract. Shock. AFTER ABSORPTION OF HIGH QUANTITIES: Disturbances of consciousness.

Chronic symptoms : ON CONTINUOUS/REPEATED EXPOSURE/CONTACT: Dry skin. Skin rash/inflammation. Possible inflammation of the respiratory tract.

### 4.3. Indication of any immediate medical attention and special treatment needed

No additional information available

## SECTION 5: Fire-fighting measures

### 5.1. Extinguishing media

Suitable extinguishing media : EXTINGUISHING MEDIA FOR SURROUNDING FIRES: Adapt extinguishing media to the environment. Foam. Dry powder. Carbon dioxide. Water spray. Sand.

Unsuitable extinguishing media : Solid water jet ineffective as extinguishing medium.

### 5.2. Special hazards arising from the substance or mixture

Fire hazard : DIRECT FIRE HAZARD. Non combustible. INDIRECT FIRE HAZARD. Reactions involving a fire hazard: see "Reactivity Hazard".

Explosion hazard : INDIRECT EXPLOSION HAZARD. Reactions with explosion hazards: see "Reactivity Hazard".

Reactivity : Violent exothermic reaction with water (moisture): (increased) risk of fire. On heating: release of corrosive gases/vapours. Absorbs the atmospheric CO2. Violent exothermic reaction with (some) acids. May be corrosive to metals. Reacts with (some) metals: release of highly flammable gases/vapours (hydrogen).

### 5.3. Advice for firefighters

Precautionary measures fire : Exposure to fire/heat: keep upwind. Exposure to fire/heat: consider evacuation. Exposure to fire/heat: have neighbourhood close doors and windows.

Firefighting instructions : Cool tanks/drums with water spray/remove them into safety. Dilute toxic gases with water spray. Take account of toxic fire-fighting water. Use water moderately and if possible collect or contain it.

Protection during firefighting : Heat/fire exposure: compressed air/oxygen apparatus.

## SECTION 6: Accidental release measures

### 6.1. Personal precautions, protective equipment and emergency procedures

#### 6.1.1. For non-emergency personnel

Protective equipment : Gloves. Face-shield. Corrosion-proof suit. Large spills/in enclosed spaces: compressed air apparatus. Large spills/in enclosed spaces: gas-tight suit. See "Material-Handling" to select protective clothing.

Emergency procedures : Mark the danger area. No naked flames. Wash contaminated clothes. Large spills/in confined spaces: consider evacuation. In case of hazardous reactions: keep upwind. In case of reactivity hazard: consider evacuation.

#### 6.1.2. For emergency responders

Protective equipment : Equip cleanup crew with proper protection.

Emergency procedures : Ventilate area.

### 6.2. Environmental precautions

Prevent soil and water pollution. Prevent spreading in sewers. Prevent entry to sewers and public waters. Notify authorities if liquid enters sewers or public waters. Avoid release to the environment.

### 6.3. Methods and material for containment and cleaning up

For containment : Contain released substance, pump into suitable containers. Consult "Material-handling" to select material of containers. Plug the leak, cut off the supply. Dam up the liquid spill. Hazardous reaction: measure explosive gas-air mixture. Reaction: dilute combustible gas/vapour with water curtain. Heat exposure: dilute toxic gas/vapour with water spray. Take account of toxic/corrosive precipitation water.

Methods for cleaning up : Take up liquid spill into absorbent material, e.g.: sand, saw dust, kieselguhr. Scoop absorbed substance into closing containers. See "Material-handling" for suitable container materials. Carefully collect the spill/leftovers. Small quantities of liquid spill: neutralize with acid solution. Wash away neutralized product with plentiful water. Damaged/cooled tanks must be emptied. Clean contaminated surfaces with an excess of water. Take collected spill to manufacturer/competent authority. Wash clothing and equipment after handling.

### 6.4. Reference to other sections

See Heading 8. Exposure controls and personal protection.

## SECTION 7: Handling and storage

### 7.1. Precautions for safe handling

Precautions for safe handling : Comply with the legal requirements. Remove contaminated clothing immediately. Clean contaminated clothing. Handle and open the container with care. Thoroughly clean/dry the installation before use. Do not discharge the waste into the drain. Keep away from naked flames/heat. Observe very strict hygiene - avoid contact. Keep container tightly closed. Measure the concentration in the air regularly. Carry operations in the open/under local exhaust/ventilation or with respiratory protection.

Hygiene measures : Wash exposed skin thoroughly after handling.

### 7.2. Conditions for safe storage, including any incompatibilities

Technical measures : Comply with applicable regulations.

Storage conditions : Keep only in the original container in a cool, well ventilated place away from : incompatible materials. Keep container closed when not in use.

Incompatible products : Strong bases. Strong acids.

Incompatible materials : Sources of ignition. Direct sunlight.

Storage temperature : > 15 °C

Heat and ignition sources : KEEP SUBSTANCE AWAY FROM: heat sources.

Prohibitions on mixed storage : KEEP SUBSTANCE AWAY FROM: combustible materials. (strong) acids. metals.

Storage area : Store in a dry area. Keep container in a well-ventilated place. Keep locked up. Protect against frost. Provide for a tub to collect spills. Unauthorized persons are not admitted. Meet the legal requirements.

Special rules on packaging : SPECIAL REQUIREMENTS: hermetical. dry. clean. correctly labelled. meet the legal requirements. Secure fragile packagings in solid containers.

Packaging materials : SUITABLE MATERIAL: stainless steel. nickel. polyethylene. polypropylene. glass. stoneware/porcelain. MATERIAL TO AVOID: lead. aluminium. copper. tin. zinc. bronze.

## SECTION 8: Exposure controls/personal protection

### 8.1. Control parameters

| **Sodium Hydroxide, 50% w/w (1310-73-2)** | | |
|---|---|---|
| OSHA | OSHA PEL (TWA) (mg/m³) | 2 mg/m³ |
| IDLH | US IDLH (mg/m³) | 10 mg/m³ |
| NIOSH | NIOSH REL (ceiling) (mg/m³) | 2 mg/m³ |

| **Sodium Hydroxide (1310-73-2)** | | |
|---|---|---|
| ACGIH | ACGIH Ceiling (mg/m³) | 2 mg/m³ (Sodium hydroxide; USA; Momentary value; TLV - Adopted Value) |
| OSHA | OSHA PEL (TWA) (mg/m³) | 2 mg/m³ |
| IDLH | US IDLH (mg/m³) | 10 mg/m³ |
| NIOSH | NIOSH REL (ceiling) (mg/m³) | 2 mg/m³ |

| **Water (7732-18-5)** |
|---|
| Not applicable |

### 8.2. Exposure controls

Appropriate engineering controls : Emergency eye wash fountains and safety showers should be available in the immediate vicinity of any potential exposure. Provide adequate general and local exhaust ventilation.

Personal protective equipment : Protective goggles. Gloves. Protective clothing. Face shield.

Materials for protective clothing : GIVE EXCELLENT RESISTANCE: nitrile rubber. GIVE GOOD RESISTANCE: No data available. GIVE LESS RESISTANCE: chlorinated polyethylene. styrene-butadiene rubber. nitrile rubber/PVC. GIVE POOR RESISTANCE: PVA. natural fibres.

Hand protection : Wear protective gloves.

| | | |
|---|---|---|
| Eye protection | : | Chemical goggles or face shield. Face shield. |
| Skin and body protection | : | Corrosion-proof clothing. |
| Respiratory protection | : | Wear gas mask with filter type B if conc. in air > exposure limit. |
| Other information | : | Do not eat, drink or smoke during use. |

## SECTION 9: Physical and chemical properties

### 9.1. Information on basic physical and chemical properties

| | | |
|---|---|---|
| Physical state | : | Liquid |
| Appearance | : | Liquid. |
| Colour | : | Colourless |
| Odour | : | Odourless |
| Odour threshold | : | No data available |
| pH | : | 14 (8 %) |
| pH solution | : | 8 % |
| Melting point | : | 12 °C |
| Freezing point | : | No data available |
| Boiling point | : | 143 °C |
| Flash point | : | Not applicable |
| Relative evaporation rate (butylacetate=1) | : | No data available |
| Flammability (solid, gas) | : | Non flammable. |
| Vapour pressure | : | 1.2 hPa (20 °C) |
| Relative vapour density at 20 °C | : | No data available |
| Relative density | : | 1.5 |
| Density | : | 1525 kg/m³ |
| Molecular mass | : | 40 g/mol |
| Solubility | : | Exothermically soluble in water. Soluble in ethanol. Soluble in methanol. Soluble in glycerol. Water: Complete |
| Log Pow | : | No data available |
| Auto-ignition temperature | : | Not applicable |
| Decomposition temperature | : | No data available |
| Viscosity, kinematic | : | No data available |
| Viscosity, dynamic | : | 79 mPa.s (20 °C) |
| Explosive limits | : | No data available |
| Explosive properties | : | Not applicable. |
| Oxidising properties | : | None. |

### 9.2. Other information

| | | |
|---|---|---|
| Minimum ignition energy | : | Not applicable |
| VOC content | : | Not applicable (inorganic) |
| Other properties | : | Clear. Hygroscopic. Slightly volatile. Substance has basic reaction. |

## SECTION 10: Stability and reactivity

### 10.1. Reactivity

Violent exothermic reaction with water (moisture): (increased) risk of fire. On heating: release of corrosive gases/vapours. Absorbs the atmospheric CO2. Violent exothermic reaction with (some) acids. May be corrosive to metals. Reacts with (some) metals: release of highly flammable gases/vapours (hydrogen).

### 10.2. Chemical stability

Stable under normal conditions. Absorbs the atmospheric CO2. Hygroscopic. Not established.

### 10.3. Possibility of hazardous reactions

Not established.

### 10.4. Conditions to avoid

Direct sunlight. Extremely high or low temperatures.

### 10.5. Incompatible materials

Strong acids. metals.

### 10.6. Hazardous decomposition products

Sodium oxide. Thermal decomposition generates : Corrosive vapours.

## SECTION 11: Toxicological information

### 11.1. Information on toxicological effects

Likely routes of exposure : Skin and eyes contact

Acute toxicity : Not classified

| Sodium Hydroxide (1310-73-2) | |
|---|---|
| ATE US (dermal) | 1350.000 mg/kg bodyweight |

| Water (7732-18-5) | |
|---|---|
| LD50 oral rat | ≥ 90000 mg/kg |
| ATE US (oral) | 90000.000 mg/kg bodyweight |

Skin corrosion/irritation : Causes severe skin burns and eye damage.
pH: 14 (8 %)

Serious eye damage/irritation : Causes serious eye damage.
pH: 14 (8 %)

Respiratory or skin sensitisation : Not classified

Germ cell mutagenicity : Not classified
Based on available data, the classification criteria are not met

Carcinogenicity : Not classified

Reproductive toxicity : Not classified
Based on available data, the classification criteria are not met

Specific target organ toxicity (single exposure) : Not classified

Specific target organ toxicity (repeated exposure) : Not classified

Aspiration hazard : Not classified

Potential adverse human health effects and symptoms : Based on available data, the classification criteria are not met.

Symptoms/injuries after inhalation : EXPOSURE TO HIGH CONCENTRATIONS: Dry/sore throat. Coughing. Irritation of the respiratory tract. Irritation of the nasal mucous membranes. FOLLOWING SYMPTOMS MAY APPEAR LATER: Possible laryngeal spasm/oedema. Risk of lung oedema. Respiratory difficulties.

Symptoms/injuries after skin contact : Caustic burns/corrosion of the skin. Slow-healing wounds.

Symptoms/injuries after eye contact : Corrosion of the eye tissue. Permanent eye damage. Causes serious eye damage.

Symptoms/injuries after ingestion : Vomiting. Diarrhoea. Burns to the gastric/intestinal mucosa. Possible esophageal perforation. Bleeding of the gastrointestinal tract. Shock. AFTER ABSORPTION OF HIGH QUANTITIES: Disturbances of consciousness.

Chronic symptoms : ON CONTINUOUS/REPEATED EXPOSURE/CONTACT: Dry skin. Skin rash/inflammation. Possible inflammation of the respiratory tract.

## SECTION 12: Ecological information

### 12.1. Toxicity

Ecology - general : Not classified as dangerous for the environment according to the criteria of Regulation (EC) No 1272/2008.

Ecology - air : Not classified as dangerous for the ozone layer (Regulation (EC) No 1005/2009). None of the known components is included in the list of fluorinated greenhouse gases (Regulation (EC) No 842/2006).

Ecology - water : Ground water pollutant. Maximum concentration in drinking water: 200 mg/l (sodium) (Directive 98/83/EC). Harmful to fishes. Harmful to invertebrates (Daphnia). pH shift.

| Sodium Hydroxide (1310-73-2) | |
|---|---|
| LC50 fish 1 | 45.4 mg/l (LC50; Other; 96 h; Salmo gairdneri; Static system; Fresh water; Experimental value) |

### 12.2. Persistence and degradability

| Sodium Hydroxide, 50% w/w (1310-73-2) | |
|---|---|
| Persistence and degradability | Biodegradability: not applicable. No (test) data on mobility of the components available. |

| Sodium Hydroxide (1310-73-2) | |
|---|---|
| Persistence and degradability | Biodegradability: not applicable. No (test)data on mobility of the substance available. |
| Biochemical oxygen demand (BOD) | Not applicable |
| Chemical oxygen demand (COD) | Not applicable |
| ThOD | Not applicable |

| Water (7732-18-5) | |
|---|---|
| Persistence and degradability | Not established. |

### 12.3. Bioaccumulative potential

| Sodium Hydroxide, 50% w/w (1310-73-2) | |
|---|---|
| Bioaccumulative potential | Does not contain bioaccumulative component(s). |

| Sodium Hydroxide (1310-73-2) | |
|---|---|
| Bioaccumulative potential | No bioaccumulation data available. |

| Water (7732-18-5) | |
|---|---|
| Bioaccumulative potential | Not established. |

### 12.4. Mobility in soil

No additional information available

### 12.5. Other adverse effects

Effect on the global warming : No known effects from this product.

GWPmix comment : No known effects from this product.

Other information : Avoid release to the environment.

## SECTION 13: Disposal considerations

### 13.1. Waste treatment methods

Waste disposal recommendations : Remove waste in accordance with local and/or national regulations. Hazardous waste shall not be mixed together with other waste. Different types of hazardous waste shall not be mixed together if this may entail a risk of pollution or create problems for the further management of the waste. Hazardous waste shall be managed responsibly. All entities that store, transport or handle hazardous waste shall take the necessary measures to prevent risks of pollution or damage to people or animals. Recycle/reuse. Remove for physico-chemical/biological treatment. Do not discharge into drains or the environment.

Additional information : LWCA (the Netherlands): KGA category 05. Hazardous waste according to Directive 2008/98/EC.

Ecology - waste materials : Avoid release to the environment.

## SECTION 14: Transport information

### Department of Transportation (DOT)

In accordance with DOT

Transport document description : UN1824 Sodium hydroxide solution, 8, II

UN-No.(DOT) : UN1824

Proper Shipping Name (DOT) : Sodium hydroxide solution

Transport hazard class(es) (DOT) : 8 - Class 8 - Corrosive material 49 CFR 173.136

Packing group (DOT) : II - Medium Danger

Hazard labels (DOT) : 8 - Corrosive

| | | |
|---|---|---|
| DOT Packaging Non Bulk (49 CFR 173.xxx) | : | 202 |
| DOT Packaging Bulk (49 CFR 173.xxx) | : | 242 |
| DOT Special Provisions (49 CFR 172.102) | : | B2 - MC 300, MC 301, MC 302, MC 303, MC 305, and MC 306 and DOT 406 cargo tanks are not authorized.<br>IB2 - Authorized IBCs: Metal (31A, 31B and 31N); Rigid plastics (31H1 and 31H2); Composite (31HZ1). Additional Requirement: Only liquids with a vapor pressure less than or equal to 110 kPa at 50 C (1.1 bar at 122 F), or 130 kPa at 55 C (1.3 bar at 131 F) are authorized.<br>N34 - Aluminum construction materials are not authorized for any part of a packaging which is normally in contact with the hazardous material.<br>T7 - 4 178.274(d)(2) Normal..... 178.275(d)(3)<br>TP2 - a. The maximum degree of filling must not exceed the degree of filling determined by the following: (image) Where: tr is the maximum mean bulk temperature during transport, tf is the temperature in degrees celsius of the liquid during filling, and a is the mean coefficient of cubical expansion of the liquid between the mean temperature of the liquid during filling (tf) and the maximum mean bulk temperature during transportation (tr) both in degrees celsius. b. For liquids transported under ambient conditions may be calculated using the formula: (image) Where: d15 and d50 are the densities (in units of mass per unit volume) of the liquid at 15 C (59 F) and 50 C (122 F), respectively. |
| DOT Packaging Exceptions (49 CFR 173.xxx) | : | 154 |
| DOT Quantity Limitations Passenger aircraft/rail (49 CFR 173.27) | : | 1 L |
| DOT Quantity Limitations Cargo aircraft only (49 CFR 175.75) | : | 30 L |
| DOT Vessel Stowage Location | : | A - The material may be stowed ‘‘on deck’’ or ‘‘under deck’’ on a cargo vessel and on a passenger vessel. |
| DOT Vessel Stowage Other | : | 52 - Stow ‘‘separated from’’ acids |
| Other information | : | No supplementary information available. |

## SECTION 15: Regulatory information

### 15.1. US Federal regulations

| **Sodium Hydroxide, 50% w/w (1310-73-2)** | |
|---|---|
| Listed on the United States TSCA (Toxic Substances Control Act) inventory<br>Not subject to reporing requirements of the United States SARA Section 313 | |
| RQ (Reportable quantity, section 304 of EPA's List of Lists) | 1000 lb |
| SARA Section 311/312 Hazard Classes | Immediate (acute) health hazard |

All components of this product are listed, or excluded from listing, on the United States Environmental Protection Agency Toxic Substances Control Act (TSCA) inventory

This product or mixture does not contain a toxic chemical or chemicals in excess of the applicable de minimis concentration as specified in 40 CFR §372.38(a) subject to the reporting requirements of section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986 and 40 CFR Part 372.

| **Sodium Hydroxide (1310-73-2)** | |
|---|---|
| RQ (Reportable quantity, section 304 of EPA's List of Lists) | 1000 lb |
| SARA Section 311/312 Hazard Classes | Immediate (acute) health hazard |

### 15.2. International regulations

#### CANADA

| **Sodium Hydroxide, 50% w/w (1310-73-2)** | |
|---|---|
| WHMIS Classification | Class E - Corrosive Material |

| **Sodium Hydroxide (1310-73-2)** | |
|---|---|
| Listed on the Canadian DSL (Domestic Substances List) | |
| WHMIS Classification | Class E - Corrosive Material |

| **Water (7732-18-5)** | |
|---|---|
| WHMIS Classification | Uncontrolled product according to WHMIS classification criteria |

#### EU-Regulations

No additional information available

### National regulations
No additional information available

### 15.3. US State regulations
California Proposition 65 - This product does not contain any substances known to the state of California to cause cancer, developmental and/or reproductive harm

## SECTION 16: Other information

Revision date : 02/07/2017

Other information : None.

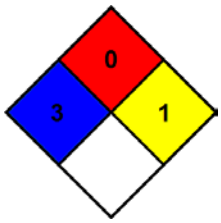
Full text of H-statements: see section 16:

| | |
|---|---|
| H312 | Harmful in contact with skin |
| H314 | Causes severe skin burns and eye damage |
| H318 | Causes serious eye damage |
| H402 | Harmful to aquatic life |

NFPA health hazard : 3 - Materials that, under emergency conditions, can cause serious or permanent injury.

NFPA fire hazard : 0 - Materials that will not burn under typical dire conditions, including intrinsically noncombustible materials such as concrete, stone, and sand.

NFPA reactivity : 1 - Materials that in themselves are normally stable but can become unstable at elevated temperatures and pressures.



HMIS III Rating

Health : 3 Serious Hazard - Major injury likely unless prompt action is taken and medical treatment is given

Flammability : 0 Minimal Hazard - Materials that will not burn

Physical : 1 Slight Hazard - Materials that are normally stable but can become unstable (self-react) at high temperatures and pressures. Materials may react non-violently with water or undergo hazardous polymerization in the absence of inhibitors.

Personal protection : H

H - Splash goggles, Gloves, Synthetic apron, Vapor respirator

COLUMBUS CHEMICAL INDUSTRIES INC.

# Safety Data Sheet

# Sulfuric Acid, 93% PC

## 1. PRODUCT AND COMPANY IDENTIFICATION

**Product Name:** Sulfuric Acid, 93% PC

**Synonyms/Generic Names:** Battery Acid, Dihydrogen Sulfate, Oil of Vitriol

**Product Number:** 5665

**Product Use:** Industrial, Manufacturing or Laboratory use

**Manufacturer:** Columbus Chemical Industries, Inc.
N4335 Temkin Rd.
Columbus, WI. 53925

**For More Information Call:** 920-623-2140 (Monday-Friday 8:00-4:30)

**In Case of Emergency Call:** CHEMTREC - 800-424-9300 or 703-527-3887 (24 Hours/Day, 7 Days/Week)

## 2. HAZARDS IDENTIFICATION

**OSHA Hazards:** Target organ effect, Corrosive

**Target Organs:** Teeth, Lungs

**Signal Words:** Danger

**Pictograms:**

**GHS Classification:**

| | |
|---|---|
| Skin corrosion | Category 1A |
| Serious eye damage | Category 1 |
| Acute aquatic toxicity | Category 3 |

**GHS Label Elements, including precautionary statements:**

**Hazard Statements:**

| | |
|---|---|
| H314 | Causes severe skin burns and eye damage. |
| H402 | Harmful to aquatic life. |

**Precautionary Statements:**

| | |
|---|---|
| P260 | Do not breathe dusts or mists. |
| P264 | Wash hands thoroughly after handling. |
| P273 | Avoid release to the environment. |
| P280 | Wear protective gloves/protective clothing/eye protection/face protection. |
| P301+P330+P331 | IF SWALLOWED: Rinse mouth. Do not induce vomiting. |

| | |
|---|---|
| P303+P361+P353 | IF ON SKIN (or hair): Take off immediately all contaminated clothing. Rinse skin with water/shower. |
| P304+P340 | IF INHALED: Remove person to fresh air and keep comfortable for breathing. |
| P305+P351+P338 | IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing. |
| P310 | Immediately call a POISON CENTER/doctor/physician. |
| P363 | Wash contaminated clothing before reuse. |
| P405 | Store locked up. |
| P501 | Dispose of contents/container in accordance with local regulations. |

**Potential Health Effects**

| | |
|---|---|
| **Eyes** | Causes severe eye burns. |
| **Inhalation** | May be harmful if inhaled. Material is extremely destructive to the tissue of the mucous membranes and upper respiratory tract. |
| **Skin** | May be harmful if absorbed through skin. Causes skin burns. |
| **Ingestion** | May be harmful if swallowed. |

**NFPA Ratings**

| | |
|---|---|
| **Health** | 3 |
| **Flammability** | 0 |
| **Reactivity** | 2 |
| **Specific hazard** | W |

**HMIS Ratings**

| | |
|---|---|
| **Health** | 3 |
| **Fire** | 0 |
| **Reactivity** | 2 |
| **Personal** | J |

## 3. COMPOSITION/INFORMATION ON INGREDIENTS

| Component | Weight % | CAS # | EINECS# / ELINCS# | Formula | Molecular Weight |
|---|---|---|---|---|---|
| Sulfuric Acid | 92-94 | 7664-93-9 | 231-939-5 | $H_2SO_4$ | 98.08 g/mol |
| Water | Balance | 7732-18-5 | 231-791-2 | $H_2O$ | 18.00 g/mol |

## 4. FIRST-AID MEASURES

| | |
|---|---|
| **Eyes** | Rinse with plenty of water for at least 15 minutes. Get medical attention immediately. |
| **Inhalation** | Move casualty to fresh air and keep at rest. If breathing is difficult, give oxygen. If not breathing, give artificial respiration. Get medical attention immediately. |
| **Skin** | Immediately flush with plenty of water for at least 15 minutes while removing contaminated clothing and wash using soap. Get medical attention immediately. |
| **Ingestion** | **Do Not Induce Vomiting!** Never give anything by mouth to an unconscious person. If conscious, wash out mouth with water. Get medical attention immediately. |

## 5. FIRE-FIGHTING MEASURES

| | |
|---|---|
| **Suitable (and unsuitable) extinguishing media** | Product is not flammable. Use appropriate media for adjacent fire. Cool containers with water. |
| **Special protective equipment and precautions for firefighters** | Wear self-contained, approved breathing apparatus and full protective clothing, including eye protection and boots. |
| **Specific hazards arising from the chemical** | Emits toxic fumes (sulfur oxides, hydrogen sulfide gas) under fire conditions. (See also Stability and Reactivity section). |

## 6. ACCIDENTAL RELEASE MEASURES

| | |
|---|---|
| **Personal precautions, protective equipment and emergency procedures** | See section 8 for recommendations on the use of personal protective equipment. |
| **Environmental precautions** | Prevent spillage from entering drains. Any release to the environment may be subject to federal/national or local reporting requirements. |
| **Methods and materials for containment and cleaning up** | Prevent spillage from entering drains. Neutralize spill with sodium bicarbonate or lime. Absorb spill with noncombustible absorbent material, then place in a suitable container for disposal. Clean surfaces thoroughly with water to remove residual contamination. Dispose of all waste and cleanup materials in accordance with regulations. |

## 7. HANDLING AND STORAGE

**Precautions for safe handling**
See section 8 for recommendations on the use of personal protective equipment. Use with adequate ventilation. Wash thoroughly after using. Keep container closed when not in use. Avoid formation of aerosols.

**Conditions for safe storage, including any incompatibilities**
Store in cool, dry well ventilated area. Keep away from incompatible materials (see section 10 for incompatibilities).

## 8. EXPOSURE CONTROLS / PERSONAL PROTECTION

**Occupational exposure controls:**

| Component | Exposure Limits | Basis | Entity |
|---|---|---|---|
| Sulfuric Acid | 0.2 $mg/m^3$ | TLV | ACGIH |
| | 1 $mg/m^3$ | PEL | OSHA |
| | 1 $mg/m^3$ | REL | NIOSH |
| | 15 $mg/m^3$ | IDLH | OSHA |

TWA: Time Weighted Average over 8 hours of work.
TLV: Threshold Limit Value over 8 hours of work.
REL: Recommended Exposure Limit
PEL: Permissible Exposure Limit
STEL: Short Term Exposure Limit during x minutes.
IDLH: Immediately Dangerous to Life or Health
WEEL: Workplace Environmental Exposure Levels
CEIL: Ceiling

**Personal Protection**

| | |
|---|---|
| **Eyes** | Wear chemical safety glasses or goggles, and face shield. |
| **Inhalation** | Provide local exhaust, preferably mechanical. If exposure levels are excessive, use an approved respirator. |
| **Skin** | Wear nitrile or rubber gloves, and full body suit. |
| **Other** | Not Available |

**Other Recommendations**
Provide eyewash stations, quick-drench showers and washing facilities accessible to areas of use and handling.

## 9. PHYSICAL AND CHEMICAL PROPERTIES

| | |
|---|---|
| Appearance (physical state, color, etc.) | Clear, colorless liquid. |
| Odor | Odorless. |
| Odor threshold | Not Available |
| pH | Not Available |
| Melting point/freezing point | Not Available |
| Initial boiling point and boiling range | Not Available |
| Flash point | Not Flammable |
| Evaporation rate | Not Available |
| Flammability (solid, gas) | Not Flammable |
| Upper/lower flammability or explosive limit | Not Explosive |
| Vapor pressure | Not Available |
| Vapor density | Not Available |
| Density | 1.8350 (water = 1) |
| Solubility (ies) | Soluble in water. |
| Partition coefficient: n-octanol/water | Not Available |
| Auto-ignition temperature | Not Available |
| Decomposition temperature | Not Available |

## 10. STABILITY AND REACTIVITY

| | |
|---|---|
| **Chemical Stability** | Stable |
| **Possibility of Hazardous Reactions** | Will not occur. |
| **Conditions to Avoid** | Moisture. |
| **Incompatible Materials** | Bases, halides, organic material, carbides, chlorates, fulminates, nitrates, picrates, cyanides, cyclopentadiene, cyclopentanone oxime, nitroaryl amines, hexalithium disilicide, phosphorus (III) oxide, powdered metals. |
| **Hazardous Decomposition Products** | Sulfur oxides, hydrogen sulfide gas. |

## 11. TOXICOLOGICAL INFORMATION

**Acute Toxicity**

*Sulfuric Acid*

| | |
|---|---|
| **Skin** | Not Available |
| **Eyes** | Not Available |
| **Respiratory** | LD50 – Rat – 510 mg/m$^3$ – 2h |
| **Ingestion** | LD50 – Rat – 2,140 mg/kg |

**Carcinogenicity**

| | |
|---|---|
| **IARC** | 1: Carcinogenic to humans (Sulfuric Acid-Aerosol). |
| **ACGIH** | A2: Suspected human carcinogen (Sulfuric Acid-Aerosol). |
| **NTP** | No components of this product present at levels greater than or equal to 0.1% is identified as a known or anticipated carcinogen by NTP. |
| **OSHA** | No components of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by OSHA. |

**Signs & Symptoms of Exposure**

| | |
|---|---|
| **Skin** | Burning, itching, redness, inflammation upon exposed tissue. |
| **Eyes** | Eye burns, watering eyes. |
| **Respiratory** | Burning, choking, coughing, shortness of breath. |
| **Ingestion** | Nausea, vomiting, diarrhea, burning, severe pain. |

| | |
|---|---|
| **Chronic Toxicity** | May cause bleeding of nose and gums, nasal and oral mucosal ulceration, conjunctivitis, yellowing of teeth and erosion of tooth enamel. |
| **Teratogenicity** | Not Available |
| **Mutagenicity** | Not Available |
| **Embryotoxicity** | Not Available |
| **Specific Target Organ Toxicity** | Not Available |
| **Reproductive Toxicity** | Not Available |
| **Respiratory/Skin Sensitization** | Not Available |

## 12. ECOLOGICAL INFORMATION

**Ecotoxicity**

*Sulfuric Acid*

| | |
|---|---|
| **Aquatic Vertebrate** | LC50 – Gambusia affinis – 42 mg/L – 96h |
| **Aquatic Invertebrate** | EC50 - Daphnia magna (Water flea) - 29 mg/l - 24 h |
| **Terrestrial** | Not Available |

| | |
|---|---|
| **Persistence and Degradability** | Not Available |
| **Bioaccumulative Potential** | Does not accumulate. |
| **Mobility in Soil** | Not Available |
| **PBT and vPvB Assessment** | Not Available |
| **Other Adverse Effects** | Not Available |

## 13. DISPOSAL CONSIDERATIONS

| | |
|---|---|
| **Waste Residues** | Users should review their operations in terms of the applicable federal/national or local regulations and consult with appropriate regulatory agencies if necessary before disposing of waste product container or residue. |
| **Product Containers** | Users should review their operations in terms of the applicable federal/national or local regulations and consult with appropriate regulatory agencies if necessary before disposing of waste product container. |

The information offered in section 13 is for the product as shipped. Use and/or alterations to the product may significantly change the characteristics of the material and alter the waste classification and proper disposal methods.

## 14. TRANSPORTATION INFORMATION

| | |
|---|---|
| US DOT | UN1830, Sulfuric acid, 8, pg II |
| TDG | UN1830, SULFURIC ACID, 8, pg II |
| IMDG | UN1830, SULFURIC ACID, 8, pg II |
| Marine Pollutant | No |
| IATA/ICAO | UN1830, Sulfuric acid, 8, pg II |

## 15. REGULATORY INFORMATION

| | |
|---|---|
| TSCA Inventory Status | All ingredients are listed on the TSCA inventory. |
| DSCL (EEC) | All ingredients are listed on the DSCL inventory. |
| California Proposition 65 | Listed: Sulfuric Acid (aerosol) |
| SARA 302 | Listed: Sulfuric Acid (aerosol) |
| SARA 304 | Listed: Sulfuric Acid (aerosol) |
| SARA 311 | Acute Health Hazard, Chronic Health Hazard |
| SARA 312 | Acute Health Hazard, Chronic Health Hazard |
| SARA 313 | Listed: Sulfuric Acid (aerosol) |
| WHMIS Canada | Class E: Corrosive material.<br>Class D-1A: Material causing other toxic effects (VERY TOXIC). |

## 16. OTHER INFORMATION

| Revision | Date |
|---|---|
| Revision 1 | 02/15/2013 |
| Revision 2 | 01/22/2015 |
| | |

Disclaimer: Columbus Chemical Industries, Inc. (“Columbus”) believes that the information herein is factual but is not intended to be all inclusive. The information relates only to the specific material designated and does not relate to its use in combination with other materials or its use as to any particular process. Because safety standards and regulations are subject to change and because Columbus has no continuing control over the material, those handling, storing or using the material should satisfy themselves that they have current information regarding the particular way the material is handled, stored or used and that the same is done in accordance with federal, state and local law. COLUMBUS MAKES NO WARRANTY, EXPRESS OR IMPLIED, INCLUDING (WITHOUT LIMITATION) WARRANTIES WITH RESPECT TO THE COMPLETENESS OR CONTINUING ACCURACY OF THE INFORMATION CONTAINED HEREIN OR WITH RESPECT TO FITNESS FOR ANY PARTICULAR USE.

## SECTION 1: Identification of the substance/mixture and of the company/undertaking

### 1.1 Product identifier

| | | |
|---|---|---|
| Trade name | : | TOLCIDE PS50A |
| FIFRA Registration number | : | 4564-17 |

### 1.2 Relevant identified uses of the substance or mixture and uses advised against

| | | |
|---|---|---|
| Uses of the Substance / Mixture | : | Specific use(s): FIFRA regulated use only., Biocidal product |

### 1.3 Details of the supplier of the safety data sheet

| | | |
|---|---|---|
| Company | : | Solvay USA Inc.,<br>NOVECARE<br>8 Cedar Brook Drive<br>Cranbury, NJ, 08512-7500, US<br>Telephone number: 800-973-7873 |

### 1.4 Emergency telephone

FOR EMERGENCIES INVOLVING A SPILL, LEAK, FIRE, EXPOSURE OR ACCIDENT CONTACT: CHEMTREC 800-424-9300 within the United States and Canada, or 703-527-3887 for international collect calls.

## SECTION 2: Hazards identification

Although OSHA has not adopted the environmental portion of the GHS regulations, this document may include information on environmental effects.

### 2.1 Classification of the substance or mixture

**HCS 2012 (29 CFR 1910.1200)**

| | |
|---|---|
| Acute toxicity, Category 4 | H302: Harmful if swallowed. |
| Acute toxicity, Category 3 | H331: Toxic if inhaled. |
| Serious eye damage, Category 1 | H318: Causes serious eye damage. |
| Skin sensitization, Category 1 | H317: May cause an allergic skin reaction. |
| Reproductive toxicity, Category 2 | H361: Suspected of damaging fertility or the unborn child. |

### 2.2 Label elements

**HCS 2012 (29 CFR 1910.1200)**

Pictogram :

| | | |
|---|---|---|
| Signal Word | : | Danger |

**Hazard Statements:**

| | |
|---|---|
| H302 | Harmful if swallowed. |
| H317 | May cause an allergic skin reaction. |
| H318 | Causes serious eye damage. |
| H331 | Toxic if inhaled. |
| H361 | Suspected of damaging fertility or the unborn child. |

**Precautionary Statements:**

Prevention

| | |
|---|---|
| P201 | Obtain special instructions before use. |
| P202 | Do not handle until all safety precautions have been read and understood. |
| P261 | Avoid breathing dust/ fume/ gas/ mist/ vapors/ spray. |
| P264 | Wash skin thoroughly after handling. |
| P270 | Do not eat, drink or smoke when using this product. |
| P271 | Use only outdoors or in a well-ventilated area. |
| P272 | Contaminated work clothing must not be allowed out of the workplace. |
| P280 | Wear eye protection/ face protection. |
| P280 | Wear protective gloves. |
| P281 | Use personal protective equipment as required. |

Response

| | |
|---|---|
| P301 + P312 | IF SWALLOWED: Call a POISON CENTER or doctor/ physician if you feel unwell. |
| P302 + P352 | IF ON SKIN: Wash with plenty of soap and water. |
| P304 + P340 | IF INHALED: Remove victim to fresh air and keep at rest in a position comfortable for breathing. |
| P305 + P351 + P338 | IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing. |
| P308 + P313 | IF exposed or concerned: Get medical advice/ attention. |
| P310 | Immediately call a POISON CENTER or doctor/ physician. |
| P330 | Rinse mouth. |
| P333 + P313 | If skin irritation or rash occurs: Get medical advice/ attention. |
| P363 | Wash contaminated clothing before reuse. |

Storage

| | |
|---|---|
| P403 + P233 | Store in a well-ventilated place. Keep container tightly closed. |
| P405 | Store locked up. |

Disposal

| | |
|---|---|
| P501 | Dispose of contents/ container to an approved waste disposal plant. |

**2.3 Other hazards which do not result in classification**

H400: Very toxic to aquatic life.
H411: Toxic to aquatic life with long lasting effects.

Possible damage to liver following repeated or prolonged exposure by ingestion.

## SECTION 3: Composition/information on ingredients

### 3.1 Substance

Not applicable, this product is a mixture.

### 3.2 Mixture

Chemical nature : Aqueous solution

**Hazardous Ingredients and Impurities**

| Chemical Name | Identification number CAS-No. | Concentration [%] |
|---|---|---|
| Tetrakis(Hydroxymethyl) Phosphonium Sulfate | 55566-30-8 | 50 |

## SECTION 4: First aid measures

### 4.1 Description of first-aid measures

General advice : Show this material safety data sheet to the doctor in attendance.
First responder needs to protect himself.
Place affected apparel in a sealed bag for subsequent decontamination.
Plan first aid action before beginning work with this product.
In the case of accident or if you feel unwell, seek medical advice immediately (show the label where possible).

If inhaled : Move to fresh air.
Keep at rest.
Consult a physician.

Skin contact : Take off contaminated clothing and shoes immediately.
Wash off with plenty of water.
Wash immediately and thoroughly for a prolonged period (at least 15 minutes).
Get medical attention if irritation develops and persists.

Eye contact : Rinse immediately with plenty of water, also under the eyelids, for at least 15 minutes.
Get immediate medical advice/ attention.

Ingestion : Do not induce vomiting without medical advice.
If victim is conscious:
Rinse mouth with water.
Keep at rest.
Never give anything by mouth to an unconscious person.
Do not leave the victim unattended.
Vomiting may occur spontaneously
Risk of product entering the lungs on vomiting after ingestion.
Lay victim on side.
Get immediate medical advice/ attention.

**4.2 Most important symptoms and effects, both acute and delayed**

| | | |
|---|---|---|
| Symptoms | : | Lachrymation<br>Ingestion may provoke the following symptoms:<br>Nausea<br>Liver disorders |
| Risks | : | Skin contact may aggravate existing skin disease |

**4.3 Indication of any immediate medical attention and special treatment needed**

| | | |
|---|---|---|
| Notes to physician | : | All treatments should be based on observed signs and symptoms of distress in the patient. Consideration should be given to the possibility that overexposure to materials other than this product may have occurred.<br><br>Treat symptomatically.<br>There is no specific antidote available. |

## SECTION 5: Firefighting measures

| | | |
|---|---|---|
| Flash point | : | Not applicable (aqueous liquid). |
| Autoignition temperature | : | Not applicable |
| Flammability / Explosive limit | : | no data available |

**5.1 Extinguishing media**

| | | |
|---|---|---|
| Suitable extinguishing media | : | In case of fire, use water/water spray/water jet/carbon dioxide/sand/foam/alcohol resistant foam/chemical powder for extinction. |
| Unsuitable extinguishing media | : | Use extinguishing measures that are appropriate to local circumstances and the surrounding environment. |

**5.2 Special hazards arising from the substance or mixture**

| | | |
|---|---|---|
| Specific hazards during fire fighting | : | Harmful or toxic vapors are released.<br>Do not allow run-off from fire fighting to enter drains or water courses.<br>Under fire conditions:<br>Will burn<br>(following evaporation of water)<br>Hazardous decomposition products<br>Phosphorus trihydride (phosphine)<br>Oxides of phosphorus<br>Sulfur oxides<br>Carbon oxides |

**5.3 Advice for firefighters**

| | | |
|---|---|---|
| Special protective equipment for fire-fighters | : | Firefighters should wear NIOSH/MSHA approved self-contained breathing apparatus and full protective clothing. |

| | | |
|---|---|---|
| | | In the event of fire, wear self-contained breathing apparatus.<br>Personal protective equipment comprising: suitable protective gloves, safety goggles and protective clothing |
| Specific fire fighting methods | : | Standard procedure for chemical fires. |
| Further information | : | Collect contaminated fire extinguishing water separately. This must not be discharged into drains.<br>Fire residues and contaminated fire extinguishing water must be disposed of in accordance with local regulations. |

## SECTION 6: Accidental release measures

### 6.1 Personal precautions, protective equipment and emergency procedures

| | | |
|---|---|---|
| Personal precautions, protective equipment and emergency procedures | : | Do not breathe spray.<br>Avoid contact with the skin and the eyes.<br>Use personal protective equipment.<br>Ensure adequate ventilation.<br>Evacuate personnel to safe areas. |

### 6.2 Environmental precautions

| | | |
|---|---|---|
| Environmental precautions | : | Do not allow uncontrolled discharge of product into the environment.<br>Contain the spilled material by diking.<br>Do not flush into surface water or sanitary sewer system.<br>Do not let product enter drains.<br>Spills may be reportable to the National Response Center (800-424-8802) and to state and/or local agencies |

### 6.3 Methods and materials for containment and cleaning up

| | | |
|---|---|---|
| Recovery | : | Contain spillage, soak up with non-combustible absorbent material, (e.g. sand, earth, diatomaceous earth, vermiculite) and transfer to a container for disposal according to local / national regulations (see section 13).<br>Keep in suitable, closed containers for disposal. |
| | : | Never return spills in original containers for re-use. |
| Decontamination / cleaning | : | Wash nonrecoverable remainder with large amounts of water.<br>Recover the cleaning water for subsequent disposal. |
| | : | Decontaminate tools, equipment and personal protective equipment in a segregated area. |
| Disposal | : | Dispose of contents/ container to an approved waste disposal plant.<br>Dispose of in accordance with local regulations. |

### 6.4 Reference to other sections

| | | |
|---|---|---|
| Reference to other sections | : | For personal protection see section 8. |

## SECTION 7: Handling and storage

### 7.1 Precautions for safe handling

| | | |
|---|---|---|
| Technical measures | : | Provide adequate ventilation. |
| Advice on safe handling and usage | : | Avoid exposure - obtain special instructions before use.<br>This product must only be handled by skilled operators.<br>Reduce the duration of exposure to the minimum required.<br><br>Avoid formation of aerosol.<br>Avoid the formation or spread of mists in the atmosphere.<br>Handle in accordance with good industrial hygiene and safety practice.<br>Use only with adequate ventilation/personal protection.<br><br>Do NOT handle without gloves. |
| Hygiene measures | : | Personal hygiene is an important work practice exposure control measure and the following general measures should be taken when working with or handling this materials:<br>1) Do not store, use, and/or consume foods, beverages, tobacco products, or cosmetics in areas where this material is stored.<br>2) Wash hands and face carefully before eating, drinking, using tobacco, applying cosmetics, or using the toilet.<br>3) Wash exposed skin promptly to remove accidental splashes or contact with material. |

### 7.2 Conditions for safe storage, including any incompatibilities

| | | |
|---|---|---|
| Technical Measures for storage | : | Prevent unauthorized access.<br>Keep container tightly closed in a dry and well-ventilated place.<br>Containers which are opened must be carefully resealed and kept upright to prevent leakage.<br>Take all necessary measures to avoid accidental discharge of products into drains and waterways due to the rupture of containers or transfer systems. |

**Storage conditions**

| | | |
|---|---|---|
| Recommended | : | Keep in a dry, cool and well-ventilated place.<br>Keep container tightly closed. |
| To be avoided | : | Keep away from incompatible materials to be indicated by the manufacturer<br>Keep away from open flames, hot surfaces and sources of ignition. |
| Incompatible products | : | Do not mix with incompatible materials (See list, section 10). |

**Packaging Measures**

| | | |
|---|---|---|
| Packaging Measures | : | Polyethylene or polypropylene drums., Stainless steel |
| Packaging materials—Recommended | : | Plastic materials (polyethylene). |
| Packaging materials—To be avoided | : | Ordinary steel. |

**Storage stability**

| | | |
|---|---|---|
| Storage temperature | : | no data available |
| Other data | : | No decomposition if stored and applied as directed. |

**7.3 Specific end use(s)**

no data available

## SECTION 8: Exposure controls/personal protection

Introductory Remarks: These recommendations provide general guidance for handling this product. Because specific work environments and material handling practices vary, safety procedures should be developed for each intended application. Assistance with selection, use and maintenance of worker protection equipment is generally available from equipment manufacturers.

**8.1 Control parameters**

**Ingredients with workplace control parameters**

| Ingredients | Value type | Value | Basis |
|---|---|---|---|
| Tetrakis(Hydroxymethyl) Phosphonium Sulfate | TWA | 2 mg/m3 | ACGIH |
| | Central nervous system, 2014 Adoption, Not classifiable as a human carcinogen | | |

**8.2 Exposure controls**

**Control measures**

| | | |
|---|---|---|
| Engineering measures | : | Where engineering controls are indicated by use conditions or a potential for excessive exposure exists, the following traditional exposure control techniques may be used to effectively minimize employee exposures :<br><br>Avoid splashes.<br>Effective exhaust ventilation system<br>Facilities and equipment easily cleanable.<br>Separate rooms are required for washing, showering and changing clothes. |

**Personal protective equipment**

| | | |
|---|---|---|
| Respiratory protection | : | When respirators are required, select NIOSH/MSHA approved equipment based on actual or potential airborne concentrations and in accordance with the appropriate regulatory standards and/or industrial recommendations.<br><br>Use a respirator with an approved filter if a risk assessment indicates this is necessary. |
| Hand protection | : | Glove material: Polyvinyl alcohol or nitrile- butyl-rubber gloves<br>Please observe the instructions regarding permeability and breakthrough time which are provided by the supplier of the gloves. Also take into consideration the specific local conditions under which the product is used, such as the danger of cuts, abrasion, and the contact time.<br>Gloves must be inspected prior to use.<br>Gloves should be discarded and replaced if there is any indication of degradation or chemical breakthrough. |
| Eye protection | : | Eye and face protection requirements will vary dependent upon work environment conditions and material handling practices. Appropriate ANSI Z87 approved equipment should be selected for the particular use intended for this material.<br><br>Eye contact should be prevented through the use of:<br><br>Safety glasses with side-shields<br>In case of contact through splashing:<br>Wear face-shield and protective suit. |
| Skin and body protection | : | Wear suitable protective clothing, gloves and eye/face protection.<br><br>Choose body protection according to the amount and concentration of the dangerous substance at the work place.<br>Remove and wash contaminated apparel. |
| Hygiene measures | : | Personal hygiene is an important work practice exposure control measure and the following general measures should be taken when working with or handling this materials:<br>1) Do not store, use, and/or consume foods, beverages, tobacco products, or cosmetics in areas where this material is stored.<br>2) Wash hands and face carefully before eating, drinking, using tobacco, applying cosmetics, or using the toilet.<br>3) Wash exposed skin promptly to remove accidental splashes or contact with material. |
| Protective measures | : | Always have on hand a first-aid kit, together with proper instructions.<br>Ensure that eyewash stations and safety showers are close to the workstation location.<br>The protective equipment must be selected in accordance with current local standards and in cooperation with the supplier of the protective equipment.<br>Selection of appropriate personal protective equipment should be based on an evaluation of the performance characteristics of the protective equipment relative to the task(s) to be performed, conditions present, duration of use, and the potential hazards, and/or risks that may occur during use. |

## SECTION 9: Physical and chemical properties

Physical and Chemical properties here represent typical properties of this product. Contact the business area using the Product information phone number in Section 1 for its exact specifications.

### 9.1 Information on basic physical and chemical properties

| | | |
|---|---|---|
| Appearance | : | Form : Aqueous solution<br>Physical state: liquid<br>Color: pale yellow to pale pink |
| Odor | : | characteristic |
| Odor Threshold | : | no data available |
| pH | : | 3.0 - 4.0 ( 1 % (m/v)) |
| Freezing point | : | < 14 °F (< -10 °C) |
| Flash point | : | Not applicable (aqueous liquid). |
| Evaporation rate (Butylacetate = 1) | : | no data available |
| Flammability (solid, gas) | : | The product is not flammable. |
| Flammability / Explosive limit | : | no data available |
| Autoignition temperature | : | Not applicable |
| Vapor pressure | : | no data available |
| Vapor density | : | no data available |
| Density | : | 1.21 - 1.29 g/cm3 ( 68 °F (20 °C)) |
| Solubility | : | Water solubility :<br>completely miscible<br><br>Solubility in other solvents:<br>not determined |
| Partition coefficient: n-octanol/water | : | log Pow: -9.8<br>THPS 75%, Structure-activity relationship (SAR), estimated<br><br>log Pow: -4.38<br>Polymer, Structure-activity relationship (SAR), estimated |
| Thermal decomposition | : | > 320 °F (160 °C) |

| | | |
|---|---|---|
| Viscosity | : | Viscosity, kinematic : 4 mm2/s ( 73 °F (23 °C)) |
| Explosive properties | : | no data available |
| Oxidizing properties | : | Not considered as oxidizing. |

**9.2 Other information**

| | | |
|---|---|---|
| Molecular weight | : | 406.3 g/mol |

## SECTION 10: Stability and reactivity

**10.1 Reactivity**

| | | |
|---|---|---|
| Reactivity | : | Stable at normal ambient temperature and pressure. |

**10.2 Chemical stability**

| | | |
|---|---|---|
| Chemical stability | : | Stable under recommended storage conditions. |

**10.3 Possibility of hazardous reactions**

No decomposition if stored and applied as directed.

| | | |
|---|---|---|
| Polymerization | : | Hazardous polymerization does not occur. |

**10.4 Conditions to avoid**

| | | |
|---|---|---|
| Conditions to avoid | : | No dangerous reaction known under conditions of normal use. |

**10.5 Incompatible materials**

| | | |
|---|---|---|
| Materials to avoid | : | Strong acids<br>Strong bases<br>Strong oxidizing agents<br>Strong reducing agents. |

**10.6 Hazardous decomposition products**

| | | |
|---|---|---|
| Decomposition products | : | Oxides of phosphorus<br>Sulfur oxides<br>Hydrogen<br>Carbon monoxide, carbon dioxide and unburned hydrocarbons (smoke).<br>PHOSPHINE |

## SECTION 11: Toxicological information

### 11.1 Information on toxicological effects

**Acute toxicity**

| | | |
|---|---|---|
| Acute oral toxicity | : | The product itself has not been tested.<br>According to the data on the components<br>According to the classification criteria for mixtures.<br>Harmful if swallowed.<br><br>LD50 : 575 mg/kg - Rat , for males and females<br>THPS 75%<br>Unpublished internal reports<br><br>LD50 : > 2,000 mg/kg - Rat<br>Polymer<br>Unpublished internal reports |
| Acute inhalation toxicity | : | The product itself has not been tested.<br>Data available only for some components.<br>According to the classification criteria for mixtures.<br>Toxic by inhalation.<br><br>LC50 - 4 h ( dust/mist ) : 0.59 mg/l - Rat , for males and females<br>THPS 75%<br>Published data |

**Skin corrosion/irritation**

Skin irritation : The product itself has not been tested.
According to the data on the components
According to the classification criteria for mixtures.
Not classified as irritating to skin

Rabbit
No skin irritation
Method: OECD Test Guideline 404
THPS 75%
Unpublished internal reports

Rabbit
Method: OECD Test Guideline 404
Unpublished internal reports
Polymer
Not classified as irritating to skin

**Serious eye damage/eye irritation**

Eye irritation : The product itself has not been tested.
According to the data on the components
According to the classification criteria for mixtures.
Risk of serious damage to eyes.

Rabbit
Risk of serious damage to eyes.
Method: OECD Test Guideline 405
THPS 75%
Unpublished internal reports

Rabbit
Method: OECD Test Guideline 405
Polymer
Not classified as irritating to eyes
Unpublished internal reports

**Respiratory or skin sensitization**

Sensitization : Magnusson and Kligman method - Guinea pig
May cause sensitization by skin contact.
THPS 75%
Unpublished internal reports

Magnusson and Kligman method - Guinea pig
Polymer
not sensitizing
Unpublished internal reports

**Mutagenicity**

Genotoxicity in vitro : According to the data on the components

Mutagenicity (Salmonella typhimurium - reverse mutation assay)
with and without metabolic activation
negative
THPS 75%
Unpublished internal reports

Mutagenicity (in vitro mammalian cytogenetic test)
Strain: CHO
with and without metabolic activation
positive
THPS 75%
Unpublished internal reports

UDS test
Strain: Hepatocyte (primary culture)
negative
THPS 75%
Unpublished internal reports

Mouse lymphoma test / TK
with and without metabolic activation
positive
THPS 75%
Unpublished internal reports

Mutagenicity (Escherichia coli - reverse mutation assay)
with and without metabolic activation
negative
Polymer
Unpublished internal reports

Genotoxicity in vivo : Data available only for some components.
Product is not considered to be genotoxic

Rodent dominant Lethal test - Rat
negative

Unpublished internal reports

In vivo micronucleus test - Mouse
negative
THPS 75%
Unpublished internal reports

**Carcinogenicity**

Carcinogenicity : Data available only for some components.

Rat Oral exposure
THPS 75%
Animal testing did not show any carcinogenic effects.
Published data

Mouse Oral exposure
THPS 75%
Animal testing did not show any carcinogenic effects.
Published data

This product does not contain any ingredient designated as probable or suspected human carcinogens by:
NTP
IARC
OSHA
ACGIH

**Toxicity for reproduction and development**

Toxicity to reproduction / fertility : Data available only for some components.

Fertility study 2 generations - Rat
Oral exposure
THPS 75%
no impairment of fertility has been observed
Unpublished internal reports

Developmental Toxicity/Teratogenicity : Data available only for some components.

Rat
Oral exposure
NOEL teratogenicity: 60 mg/kg
NOEL maternal: 15 mg/kg

THPS 75%
Unpublished internal reports

Rabbit
Oral exposure
NOEL teratogenicity: 18 mg/kg
NOEL maternal: 18 mg/kg

THPS 75%
Effects on development were observed
Unpublished internal reports

**STOT**

STOT-single exposure : Toxicology Assessment:
The substance or mixture is not classified as specific target organ toxicant, single exposure.

STOT-repeated exposure : Toxicology Assessment:

The substance or mixture is not classified as specific target organ toxicant, repeated exposure.

Data available only for some components.

Oral exposure 90 Days - Rat , for males and females
NOEL: 1 mg/kg
THPS 75%
Liver toxicity
Unpublished internal reports

**Neurological effects**

Neurological effects : THPS 75%, The product does not induce inhibition, Screening biochemistry test kit for cholinesterase activity inhibition

Carcinogenicity

Tetrakis(Hydroxymethyl) Phosphonium Sulfate : The product is not considered to be carcinogenic.

Teratogenicity

Tetrakis(Hydroxymethyl) Phosphonium Sulfate : Suspected human reproductive toxicant

**Aspiration toxicity**

Aspiration toxicity : no data available

## SECTION 12: Ecological information

Environment assessment : According to the classification criteria for mixtures.
Very toxic to aquatic life.
Toxic to aquatic life with long lasting effects.

## SECTION 13: Disposal considerations

**13.1 Waste treatment methods**

**Product Disposal**

Advice on Disposal : Chemical additions, processing or otherwise altering this material may make the waste management information presented in this MSDS incomplete, inaccurate or otherwise inappropriate. Please be advised that state and local requirements for waste disposal may be more restrictive or otherwise different from federal laws and regulations. Consult state and local regulations regarding the proper disposal of this material.

Waste Code : EPA:
Hazardous Waste – NO

**Advice on cleaning and disposal of packaging**

Advice : Take preliminary precautions based on the dangerous properties of the product.
Empty the packaging completely prior to disposal.
Empty containers should be taken to an approved waste handling site for recycling or disposal.
The user's attention is drawn to the possible existence of local regulations regarding disposal.

## SECTION 14: Transport information

Transportation status: IMPORTANT! Statements below provide additional data on listed transport classification.
The listed Transportation Classification does not address regulatory variations due to changes in package size, mode of shipment or other regulatory descriptors.

**DOT**

**14.1 UN number** UN 2810

**14.2 Dangerous Good Description** UN 2810 TOXIC, LIQUIDS, ORGANIC, N.O.S. (tetrakis(hydroxymethyl) phosphonium sulphate), 6.1, III

**14.3 Transport hazard class** 6.1

**14.4 Packing group**

| | |
|---|---|
| Packing group | III |
| Label(s) | 6.1 |

Re: Discharge to Ground Water Authorization
PPG Industries (COPR)
Garfield Avenue Group and Former Halladay Street Gas Works
900 Garfield Avenue; Block: 21501, Lots: 16, 17, 18, 19, and 20
Jersey City, Hudson County
NJ Program Interest Numbers: G000005480
Subject Item ID: DGWD0000167709

Dear Mr. Terril:

This New Jersey Pollutant Discharge Elimination System/Discharge to Ground Water (NJPDES/DGW) authorization is hereby issued under the authority of the New Jersey Water Pollution Control Act, N.J.S.A. 58:10A-1 et seq. and the implementing regulations, N.J.A.C. 7:14A-1 et seq. N.J.A.C. 7:14A-7.5 authorizes the discharge described below which will allow the recovery and treatment of contaminated ground water, as well as implementation of in-situ remediation of contaminated ground water at the above referenced site.

Pursuant to N.J.A.C. 7:14A-22.4(b)5, a Treatment Works Approval is not required for discharges to ground water authorized pursuant to N.J.A.C. 7:14A-7.5 or 8.5 and a licensed operator is not required pursuant to N.J.A.C. 7:10A-1.10(c)1. The discharge shall be conducted as proposed in the February 2019 *Groundwater Interim Remedial Measure (IRM): Phase II Design and Permit-By-Rule (PBR) Authorization Request*, received on 28 February 2019 and clarified and revised as described in the email correspondence of 11 April 2019. This document and supporting clarification information was submitted by Cullen Flanders, Andrew Fuller, Matthew Schnobrich, and John Horst of Arcadis U.S. Inc., on behalf of PPG Industries.

A public notice describing this discharge was published in The Jersey Journal on 20 March 2019 which initiated a 30-day public comment period. In addition, a copy of the public notice has been sent to the Municipal Clerk and designated local health official for Jersey City and Hudson County. The Department did not receive any comments on the DGW proposal.

Pursuant to N.J.A.C. 7:14A-2.7 the maximum approved discharge duration is five (5) years from the date of this letter, regardless of the date when the discharge first occurs. The Department shall be notified of the date when the discharge begins as instructed in section IV of this letter. Only the discharge described in Section I below is authorized. The discharge shall be conducted in conformance with the above mentioned DGW proposal and shall comply with the requirements of Sections II, III, and IV, farther below.

## I. DISCHARGE DESCRIPTION

The authorized discharge includes organic carbon substrate (e.g., molasses and/or emulsified vegetable oil [EVO]) which will be mixed with treated groundwater recovered from the site. Groundwater will be recovered from the northern portion of Site 114, from an area containing the highest total chromium (Cr) and hexavalent chromium [Cr(VI)] concentrations, and will also be recovered from areas in southern Site 114 to enhance the organic carbon recirculation program. Groundwater will be treated using an on-site water treatment plant to provide direct treatment of Cr and Cr(VI). Treatment of the recovered water will also make it suitable for re-injection with organic carbon substrate.

The treated water will be amended with substrates to provide a degradable source of organic carbon within the subsurface to support an in situ anaerobic bioprecipitation (ISAB) approach. Both dilute organic carbon and treated water will be reinjected in the southern portion of Site 114, where concentrations of Cr are lower and more amenable to rapid bioremediation. The organic carbon will stimulate several primary mechanisms that: (1) promote the in-situ reduction of Cr(VI) to trivalent Cr (Cr[III]); and (2) support the development of an environment that enables the precipitation and fixation of Cr within the aquifer matrix.

Within the reactive zone, fermentation of the organic carbon substrate promotes development of iron- and sulfate-reducing groundwater conditions that are favorable for the reduction of Cr(VI). Under these conditions, Cr(VI) is reduced to Cr(III) through reactions with multiple biologically generated reductants or via direct anaerobic respiration with Cr(VI) serving as the terminal electron acceptor. Specifically, Cr(VI) is reduced to form less soluble Cr(III)-hydroxide.

The combination of groundwater extraction from the northern area of Site 114 and portions of southern Site 114 with reinjection in southern Site 114 will help maintain the hydraulic balance inside the sheet pile enclosure around Site 114 and may also support flushing of Cr mass toward the extraction wells to speed up the reduction of Cr concentrations in the groundwater.

The IRM Phase II operation is anticipated to start in second quarter of 2019 and last for a duration of up to approximately 12 months, followed by a post-operational monitoring of 2 years. However, this will be evaluated as the program proceeds, and modifications may be requested.

It is expected that the average organic carbon dosing over the course of the 12-month Phase II program is 0.5% by volume that will be delivered during 6-hour weekday pulsing cycles. Based on the projected total recirculation volume of 31.5 million gallons of groundwater, the organic carbon demands for Phase II will be no more than 158,000 gallons of substrate (either molasses, EVO, or a combination of both). The actual dosing strength of these organic carbon substrates, the dosing durations per day (or per week), and the timing of molasses and EVO use will be determined based on monitoring observations. Groundwater recovered from Site 114 and treated at the water treatment plant will serve as the primary source of reinjection water over the course of the Phase II IRM, but potable water from an on-site source will also be used, especially during warmer periods, to reduce the incidence of biofouling.

Reagent flexibility is considered a key consideration for maximizing overall treatment during the IRM Program. While the carbon substrates above will serve as the primary reagents for use, other reagents are being included in this PBR to allow flexibility in the event that unique areas of the site are better suited to their application. Both FerroBlack®-H (a water-based suspension of 7 to 8% by weight ferrous sulfide and 1 to 2% by weight sodium hydrosulfide) and $CaS_x$ (calcium polysulfide) were used to achieve treatment during prior pilot test activities, and these reagents are retained for potential consideration during Phase II. $CaS_x$ could be delivered via the recirculation network as a soluble reagent for in situ chemical reduction (ISCR) in select areas of Site 114 in lieu of, prior to, or following use of carbon substrate. In addition to these two reagents, ferrous sulfate heptahydrate may also be used as a supplement to the carbon substrate source to provide additional iron and sulfide to further enhance Cr abiotic reduction mechanisms. As applicable, other equivalent reagents capable of reducing Cr may also be considered during the Phase II IRM and if used, would be detailed in a modification to this PBR.

The planned Phase II IRM design consists of 144 new injection wells and 20 new groundwater extraction wells. However, up to 160 total injection wells and 30 total extraction wells may be installed if needed. Using a combination of hollow stem auger (HSA) and mud rotary drilling techniques (or similar equivalent drilling technologies), wells will be constructed with 4-inch stainless steel screens. Individual well screen lengths are proposed to range between 5 to 20 feet in length, which will be further refined based on high-resolution sampling results obtained during the drilling program. Similar to the Phase I IRM well installation, injection/extraction wells may entail longer well screens up to 20 feet in length to overwhelm potential heterogeneities within the intermediate and deep soils and allow propagation of the reactive through the soils of higher relative permeability. Intermediate-depth wells are expected to reach approximate depths of between 20 to 40 feet below ground surface (bgs). Deep water-bearing zone wells will be constructed with 4-inch stainless steel, 10-slot, 20-foot screens between 45 to 65 feet bgs. Actual length of screen, screen size and general depths are free to change based on pre-design testing and field observations.

Based on previous hydraulic testing and Phase I observations, it is assumed that average extraction rates per well may be up to 3 gallons per minute (gpm). The Phase II design estimates a combined total recirculation rate (both extraction and injection) of 21 gpm and 12 gpm within the northern and southeastern areas, respectively. Where achievable, injection and extraction rates will be increased to maximize the total quantity of groundwater extracted and injected within the capabilities of both treatment areas (40 gpm each). Based on previous testing at the site and the common ratios of injection well capacity relative to injection wells, it is estimated

that injection rates may vary between 0.5 to 3 gpm per well. Injection wells may be operated at higher flow rates, depending on the nature of the soil formation and ability to receive fluids. Over the course of operation, the Phase II design entails initiation of injection activities within the northern end of Site 114, followed by gradual southward shifts in operating wells. Based on the model flow rates, these have been conceptualized as three, 8-week cycles. Similarly, injection activities in the southeastern area will gradually shift further east during the Phase II operation. Individual cycles may be extended in length (e.g., to 12 or 16 weeks) based on performance and observed reactive zone development.

The treatment of groundwater used for reinjection will be sufficient to achieve either 95% reduction of influent levels (e.g., primarily for Cr and Cr[VI]) or concentrations below the applicable Ground Water Quality Standard (GWQS) values (e.g., for Cr, Cr[VI], and other compounds with historical detections) in the effluent of the water treatment plant, whichever is less stringent. A groundwater Classification Exception Area (CEA) was established on 7 June 2018, which allows for the discharge of water containing Cr, Cr(VI), metals, volatile organic compounds (VOCs), and semi-volatile organic compounds (SVOCs) which may not be treated to levels below the GWQS by the water treatment plant prior to re-injection. The compounds other than Cr and Cr(VI) that were historically detected above the respective GWQS in the shallow, intermediate, and deep water-bearing zones are listed in the table below. Groundwater generated from the shallow water-bearing zone during soil excavation dewatering will be combined with groundwater extracted from the intermediate and deep water-bearing zones and treated with the water treatment plant. The CEA comprises the entirety of the project area (Block 21501, Lots 16 through 20), and extends to a depth of 100 feet below ground surface.

## II. SYSTEM OPERATION AND MONITORING

The area of discharge shall be monitored for evidence of malfunction. Said evidence shall include, but is not limited to: injection solution observation at land surface, wet areas, ponding, odors, and elevated photoionization detector (PID) readings in the nearby work area or building. If encountered, appropriate controls and system modification will be implemented.

The discharge shall not cause any of the following negative impacts: adverse impact on the behavior of free product or the plume; adverse impacts to a water supply well or have a long term adverse impact on ground water quality; create an unpermitted discharge to any surface water of the State or violation of Surface Water Quality Standards; create a persistent standing, ponded or surface-flowing fluid condition; or cause adverse vapor intrusion to occur.

Pursuant to N.J.A.C. 7:14A-6.2(a)5 and 11, if free product in ground water, vapors or odors in any building, or any malfunction resulting in a potential impact to a receptor are detected and are a result of the discharge authorized by this approval, the discharger will immediately: (1) cease the discharge or make necessary adjustments to the discharge rate or system operation; and (2) repair or mitigate any negative impacts.

After completion of the discharge, the property returned to its previous condition, or as agreed to with property owner if the permittee is not the property owner. All UIC-Class V injection wells shall be properly abandoned in accordance with N.J.A.C. 7:14A-8.16(d)1 as applicable. The permittee will comply with any applicable provisions of the Additional Conditions Applicable to Class I, II, III and V UIC Permits of the NJPDES regulations, N.J.A.C. 7:14A-8.9, et seq. when UIC-Class V injection well units (i.e., the injection points) are used.

## III. GROUND WATER MONITORING REQUIREMENTS

The Permittee shall perform the following ground water sampling as was specified in the DGW proposal (including all addendums and modifications) for the purpose of complying with this Discharge to Ground Water Permit-By-Rule authorization.

Baseline Sampling, before injection:

Prior to the startup of Phase II operations, but following the installation of the remediation well network and new monitoring well locations, samples will be collected for baseline analysis to establish the starting conditions for IRM treatment performance review. In accordance with the attached Table 1, baseline samples will be collected for TAL metals (total and dissolved); Cr(VI) (total and dissolved); key geochemical parameters (sulfate/sulfide and methane); total organic carbon (TOC), field parameters (pH, specific conductivity, dissolved oxygen [DO], oxidation-reduction potential [ORP], turbidity, and temperature); and depth to groundwater.

Baseline samples will be collected using the low-flow sampling method. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be

gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 micrometer (μm) filters in the field.

Operational and Treatment Monitoring, during the injections:

The operational monitoring program will be used to assess ongoing remedial system performance in support of guiding potential modifications to injection and extraction flow rates, recirculation well balancing, carbon dosing and timing, and to pre-emptively guide potential biofouling management and well redevelopment.

Operational monitoring will be performed at variable frequencies (weekly, biweekly, or monthly), as necessary, over the course of operation pursuant to Table 1. Measurements may be periodically performed more frequently than specified in Table 1 to support potential troubleshooting activities over the course of operation. Given the adaptive nature of the recirculation program and the sequencing of different groupings of injection and extraction wells during operation, it is anticipated that the operational sampling frequency of existing monitoring wells will be adapted over time. As an example, monitoring wells located within the northernmost area of Site 114 are most relevant for operational monitoring during the first step of recirculation activities. Following this initial period and the transition to more southerly injection wells, the frequency and parameter list of the initial monitoring locations may be reduced to maintain remedial efficiency, as applicable, subject to NJDEP approval. For the operational monitoring, analytical data and field parameter measurements for extracted and treated groundwater will be collected at operating extraction wells from sampling ports located at the wellheads or at the influent to the water treatment system.

Overall Phase II remedial performance will be documented via ongoing treatment monitoring during the 12-month IRM program. Sampling parameters will be collected to verify organic carbon distribution, assess the development of reduced geochemical groundwater conditions within the subsurface, and confirm corresponding declines in total Cr and Cr(VI). Evaluation of these parameters will confirm development of the subsurface reactive zone and will be used to guide carbon substrate dosing strength and frequency. This will enable treatment optimization and confirmation prior to transitioning the operating recirculation wells to subsequent steps. A summary of the analytical and field parameter measurements for treatment sampling is provided in Table 1.

Similar to the operational monitoring specifications, treatment monitoring parameters will be collected at specified frequency based on the relevance of a given parameter to operation and optimization activities. TOC and field parameter sampling is proposed most frequently (biweekly to monthly) to effectively gauge propagation of both carbon substrate and geochemical influence within the subsurface. Total Cr and Cr(VI) and select geochemical parameters (ferrous [dissolved] iron, dissolved manganese, sulfate) will be collected monthly to enable the collection of at least one to two samples between recirculation well steps. Methane sampling is also proposed, albeit less

frequently, to confirm the overall extent of reduced groundwater conditions. Similar to the sampling frequency considerations presented for the operational monitoring program, treatment monitoring parameters will be collected at a specified frequency based on the relevance of a given parameter to operation and optimization activities.

Treatment monitoring samples will be collected using the low-flow sampling method and select wells may be sampled at 5-foot intervals. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 μm filters in the field.

Post Treatment Sampling, after completion of injections:

Following the 12-month Phase II operational program, post-treatment monitoring will be used to document overall Cr treatment performance, confirm the residual reactive zone reduction capacity (via residual TOC and reduced geochemistry species), and develop an appropriate data set to demonstrate ongoing natural attenuation of any residual total Cr and Cr(VI). Post-treatment sampling will be performed in accordance with Table 1.

Treatment monitoring samples will be collected using the low-flow sampling method and select screen locations with wells will be sampled at 5-foot intervals. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system – or containerized and disposed of off-site, as appropriate. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 μm filters in the field.

Post-treatment sampling activities will be performed on a quarterly basis over a total duration of two years.

Pursuant to the Tech Regs, the Permittee shall measure ground water elevations at all sampled wells during each sampling event and shall construct ground water flow maps with the water elevation data to document the direction of ground water flow. Any non-aqueous phase liquid (NAPL) observed, including sheen, shall be documented and the NJDEP shall be notified. The Permittee shall check for both light non-aqueous phase liquid (LNAPL) and dense non-aqueous phase liquid (DNAPL). If NAPL is identified in thicknesses greater than 0.01 feet in wells planned for injection use during baseline gauging or subsequent routine performance monitoring activities, these wells will be operated first as extraction wells to facilitate NAPL recovery and removal. NAPL will be recovered and modifications will be made to allow oil separation prior to transfer to the water treatment system. Prior to converting these wells for injection use, extraction will be discontinued to allow static gauging for NAPL reoccurrence. If NAPL is not observed with thicknesses in excess of 0.01 feet for two consecutive gauging events, and the NJDEP concurs, then NAPL will be considered eliminated or recovered to the extent practicable and wells will be deemed acceptable for injection use. Alternatively, if NAPL is identified in

excess of 0.01 feet in thickness but is considered no longer recoverable (or immobile), and the NJDEP concurs, the NAPL will be considered recovered to the extent practicable and wells may also be deemed acceptable for injection use.

All sampling shall be performed as proposed and consistent with the methods specified in the most current edition of the Department's Field Sampling Procedures Manual. All samples shall be analyzed by a New Jersey Certified Laboratory certified for the methods being used to analyze groundwater samples. Analytical method MDLs shall be less than or equal to the ground water quality standards (N.J.A.C. 7:9C-1.7). Parameters determined in the field (pH, specific conductance, dissolved oxygen, temperature) are to be measured by a certified contractor or laboratory.

Comparison to the VI screening levels is necessary in order to monitor whether or not the discharge activities have the potential to cause VI issues within any nearby structures by means of adversely impacting the behavior of the ground-water contaminants (e.g., unexpected contaminant movement). If there are any exceedances of the VI screening levels caused by the authorized discharge, a VI evaluation shall be conducted of any potentially impacted structures.

Compliance with N.J.A.C. 7:26E-5.7(b) requires that the Permittee satisfy the post-injection ground water monitoring requirements that are set forth in this letter before applying for any Remedial Action Permit for Ground Water. If a Remedial Action Permit application is submitted before the required ground water sampling has been completed, the application will be denied.

Additionally, contingency compliance ground water sampling is required if ground water sampling results indicate that GWQS have been contravened because of the authorized discharge (e.g., the GWQS for sulfate is exceeded as a result of calcium polysulfide injection, or the GWQS for iron is exceeded as a result of FerroBlack®-H injection), or that ground water quality has not returned to baseline conditions (when baseline concentrations are greater than GWQS) in the expected timeframe. Ground water sampling must continue until it can be demonstrated that the GWQS have been met or until the ground water quality has returned to baseline conditions. To demonstrate either of these conditions, a minimum of two consecutive ground water sampling events spaced far enough apart to account for seasonal fluctuations, must be conducted.

Furthermore, if the Permittee is planning to apply for a Ground Water Remedial Action Permit for Natural Attenuation in the future, and exceedances of the GWQS that are due to the discharge remain, those exceedances must be treated similarly to any other site related contaminants (i.e., a sufficient number of samples is required and a decreasing concentration trend must be evident) consistent with the Department's Remedial Action Permits for Ground Water Guidance.

## IV. REPORTING REQUIREMENTS AND INFORMATION SUBMITTALS

Details of the supplemental pre-design testing, well and system installation, system operation, and performance monitoring results associated with the IRM Phase II program will be documented as part of a quarterly technical status reports submitted to the NJDEP. These quarterly status reports will include succinct, high-level summaries of activities performed, data collected, adaptive steps taken to modify or optimize Phase II treatment, and an overview of activities planned for the subsequent quarter.

Succinct performance summary results will be submitted as part of quarterly status reports. All information, including a complete summary of the work performed under the PBR, a complete set of the data collected, a summary of data trends, an evaluation and interpretation of the data, and conclusions reached (as well as the QA/QC package specified at N.J.A.C. 7:26E-2.1(a)15) shall be submitted as part of the completion report within 6 months following cessation of active Phase II operation. All information shall be submitted to:

NEW JERSEY DEPARTMENT OF ENVIRONMENTAL PROTECTION
BUREAU OF CASE ASSIGNMENT & INITIAL NOTICE
MAILCODE 401-05H
P.O. BOX 420
TRENTON, NJ 08625-0420
ATTN: COPR

Consistent with N.J.A.C. 7:14A-2.11(a) and 6.2(a)14, within 90 days after initiation of the discharge, notify the Department of the "start date" of the discharge. To report this date, send an email to Wayne.Howitz@dep.nj.gov stating the start date of the discharge.

Consistent with N.J.A.C. 7:14A-2.11(a) and 6.2(a)14, any malfunctions or non-compliance should be reported by fax or telephone within 24 hours to Wayne Howitz of the Site Remediation Program at (609) 984-2905, and in writing within 7 days to the above address using the subject line "DGW Permit-by-Rule Compliance Report - COPR." Written submissions must include the facility name and PI Number. Failure to report this information is a violation of N.J.A.C. 7:14A and the permit-by-rule.

If you have any questions or concerns, please contact Wayne C. Howitz of the Site Remediation Program at (609) 984-2905.

Sincerely,

Wayne C. Howitz, Assistant Director
Remediation Oversight Element

| **Date:** | January 19, 2021 | **Project Number:** | 60624321 |
| **Project Reference:** | PPG Phase II GW IRM | | |

This memorandum (memo) presents a request for the proposed modification of the Groundwater Interim Remedial Measure (IRM) Phase II Design Permit-by-Rule (PBR) (Attachment 1) that was approved by the New Jersey Department of Environmental (NJDEP) on 9 May 2019 for the Garfield Avenue Group Sites located in Jersey City, New Jersey.

An excerpt from the PBR states that:

> *"If NAPL is identified in thicknesses greater than 0.01 feet in wells planned for injection use during baseline gauging or subsequent routine performance monitoring activities, these wells will be operated first as extraction wells to facilitate NAPL recovery and removal..."* [NAPL = non-aqueous phase liquid]

The PBR further states that:

> *"…Alternatively, if NAPL is identified in excess of 0.01 feet in thickness but is considered no longer recoverable (or immobile), and the NJDEP concurs, the NAPL will be considered recovered to the extent practicable and wells may also be deemed acceptable for injection use" .*

As discussed during the 17 December 2020 conference call, there are at least 20 wells (injection, monitoring, and extraction wells) with dense non-aqueous phase liquids (DNAPL) present in the bottom of the wells ranging in thickness from 2 inches to as much as 15 feet (Figure 1). Also discussed were the following points:

- DNAPL in the formation is limited to thin, discrete lenses within the intermediate and deep water-bearing zones. Measured amounts of DNAPL in the wells are not representative of a similarly "thick," saturated DNAPL zone within these water-bearing zones.

AECOM
30 Knightsbridge Road, Suite 520
Piscataway, New Jersey 08854
www.aecom.com

- Removal of DNAPL to thicknesses less than 0.01 feet before commencement of the IRM is not practical within the established timeframe for the IRM Phase II.
- The low injection pressures currently used to inject reagent into the formation for the Phase II IRM will allow the reagent to flow around the DNAPL lenses rather than displace the DNAPL, thereby allowing injectant to enter permeable areas of chromium-impacted groundwater within the IRM area.
- While some movement of DNAPL may occur during the IRM injections, it is expected to be localized and to remain within the area bounded by sheet pile.

**PBR Modification Request**

In order to commence the Phase II IRM program in the southeastern area of Site 114, PPG requests that the Phase II IRM PBR be modified to allow the following:

- DNAPL in existing injection, groundwater extraction, and monitoring wells will be pumped out from the wells to the extent possible, followed by commencement of the Phase II IRM reagent injections and groundwater extraction in select wells. One or more groundwater extraction wells may be converted to reagent injection wells to treat groundwater and will be determined based on operation and treatment monitoring.
- Injection wells will be monitored for DNAPL accumulation by observing injection pressures and flow rates. If DNAPL accumulation is suspected, the reagent injection at those wells will be temporarily stopped and DNAPL will be removed. The wells will then be returned to service.
- The Phase II IRM monitoring wells will be periodically gauged for DNAPL. DNAPL will be pumped out from these monitoring wells to the extent possible and as needed in order to continue monitoring activities. The frequency of the gauging and removal events in monitoring wells will be determined based on findings during the treatment period.

Upon your email approval of this modification request, PPG will commence the Phase II IRM treatment in the southeastern area as described above.

Jersey City, Hudson County
NJ Program Interest Numbers: G000005480
Subject Item ID: DGWD0000167709

Dear Mr. Terril:

This New Jersey Pollutant Discharge Elimination System/Discharge to Ground Water (NJPDES/DGW) authorization is hereby issued under the authority of the New Jersey Water Pollution Control Act, N.J.S.A. 58:10A-1 et seq. and the implementing regulations, N.J.A.C. 7:14A-1 et seq. N.J.A.C. 7:14A-7.5 authorizes the discharge described below which will allow the recovery and treatment of contaminated ground water, as well as implementation of in-situ remediation of contaminated ground water at the above referenced site.

Pursuant to N.J.A.C. 7:14A-22.4(b)5, a Treatment Works Approval is not required for discharges to ground water authorized pursuant to N.J.A.C. 7:14A-7.5 or 8.5 and a licensed operator is not required pursuant to N.J.A.C. 7:10A-1.10(c)1. The discharge shall be conducted as proposed in the February 2019 *Groundwater Interim Remedial Measure (IRM): Phase II Design and Permit-By-Rule (PBR) Authorization Request*, received on 28 February 2019 and clarified and revised as described in the email correspondence of 11 April 2019. This document and supporting clarification information was submitted by Cullen Flanders, Andrew Fuller, Matthew Schnobrich, and John Horst of Arcadis U.S. Inc., on behalf of PPG Industries.

A public notice describing this discharge was published in The Jersey Journal on 20 March 2019 which initiated a 30-day public comment period. In addition, a copy of the public notice has been sent to the Municipal Clerk and designated local health official for Jersey City and Hudson County. The Department did not receive any comments on the DGW proposal.

Pursuant to N.J.A.C. 7:14A-2.7 the maximum approved discharge duration is five (5) years from the date of this letter, regardless of the date when the discharge first occurs. The Department shall be notified of the date when the discharge begins as instructed in section IV of this letter. Only the discharge described in Section I below is authorized. The discharge shall be conducted in conformance with the above mentioned DGW proposal and shall comply with the requirements of Sections II, III, and IV, farther below.

## I. DISCHARGE DESCRIPTION

The authorized discharge includes organic carbon substrate (e.g., molasses and/or emulsified vegetable oil [EVO]) which will be mixed with treated groundwater recovered from the site. Groundwater will be recovered from the northern portion of Site 114, from an area containing the highest total chromium (Cr) and hexavalent chromium [Cr(VI)] concentrations, and will also be recovered from areas in southern Site 114 to enhance the organic carbon recirculation program. Groundwater will be treated using an on-site water treatment plant to provide direct treatment of Cr and Cr(VI). Treatment of the recovered water will also make it suitable for re-injection with organic carbon substrate.

The treated water will be amended with substrates to provide a degradable source of organic carbon within the subsurface to support an in situ anaerobic bioprecipitation (ISAB) approach. Both dilute organic carbon and treated water will be reinjected in the southern portion of Site 114, where concentrations of Cr are lower and more amenable to rapid bioremediation. The organic carbon will stimulate several primary mechanisms that: (1) promote the in-situ reduction of Cr(VI) to trivalent Cr (Cr[III]); and (2) support the development of an environment that enables the precipitation and fixation of Cr within the aquifer matrix.

Within the reactive zone, fermentation of the organic carbon substrate promotes development of iron- and sulfate-reducing groundwater conditions that are favorable for the reduction of Cr(VI). Under these conditions, Cr(VI) is reduced to Cr(III) through reactions with multiple biologically generated reductants or via direct anaerobic respiration with Cr(VI) serving as the terminal electron acceptor. Specifically, Cr(VI) is reduced to form less soluble Cr(III)-hydroxide.

The combination of groundwater extraction from the northern area of Site 114 and portions of southern Site 114 with reinjection in southern Site 114 will help maintain the hydraulic balance inside the sheet pile enclosure around Site 114 and may also support flushing of Cr mass toward the extraction wells to speed up the reduction of Cr concentrations in the groundwater.

The IRM Phase II operation is anticipated to start in second quarter of 2019 and last for a duration of up to approximately 12 months, followed by a post-operational monitoring of 2 years. However, this will be evaluated as the program proceeds, and modifications may be requested.

It is expected that the average organic carbon dosing over the course of the 12-month Phase II program is 0.5% by volume that will be delivered during 6-hour weekday pulsing cycles. Based on the projected total recirculation volume of 31.5 million gallons of groundwater, the organic carbon demands for Phase II will be no more than 158,000 gallons of substrate (either molasses, EVO, or a combination of both). The actual dosing strength of these organic carbon substrates, the dosing durations per day (or per week), and the timing of molasses and EVO use will be determined based on monitoring observations. Groundwater recovered from Site 114 and treated at the water treatment plant will serve as the primary source of reinjection water over the course of the Phase II IRM, but potable water from an on-site source will also be used, especially during warmer periods, to reduce the incidence of biofouling.

Reagent flexibility is considered a key consideration for maximizing overall treatment during the IRM Program. While the carbon substrates above will serve as the primary reagents for use, other reagents are being included in this PBR to allow flexibility in the event that unique areas of the site are better suited to their application. Both FerroBlack®-H (a water-based suspension of 7 to 8% by weight ferrous sulfide and 1 to 2% by weight sodium hydrosulfide) and $CaS_x$ (calcium polysulfide) were used to achieve treatment during prior pilot test activities, and these reagents are retained for potential consideration during Phase II. $CaS_x$ could be delivered via the recirculation network as a soluble reagent for in situ chemical reduction (ISCR) in select areas of Site 114 in lieu of, prior to, or following use of carbon substrate. In addition to these two reagents, ferrous sulfate heptahydrate may also be used as a supplement to the carbon substrate source to provide additional iron and sulfide to further enhance Cr abiotic reduction mechanisms. As applicable, other equivalent reagents capable of reducing Cr may also be considered during the Phase II IRM and if used, would be detailed in a modification to this PBR.

The planned Phase II IRM design consists of 144 new injection wells and 20 new groundwater extraction wells. However, up to 160 total injection wells and 30 total extraction wells may be installed if needed. Using a combination of hollow stem auger (HSA) and mud rotary drilling techniques (or similar equivalent drilling technologies), wells will be constructed with 4-inch stainless steel screens. Individual well screen lengths are proposed to range between 5 to 20 feet in length, which will be further refined based on high-resolution sampling results obtained during the drilling program. Similar to the Phase I IRM well installation, injection/extraction wells may entail longer well screens up to 20 feet in length to overwhelm potential heterogeneities within the intermediate and deep soils and allow propagation of the reactive through the soils of higher relative permeability. Intermediate-depth wells are expected to reach approximate depths of between 20 to 40 feet below ground surface (bgs). Deep water-bearing zone wells will be constructed with 4-inch stainless steel, 10-slot, 20-foot screens between 45 to 65 feet bgs. Actual length of screen, screen size and general depths are free to change based on pre-design testing and field observations.

Based on previous hydraulic testing and Phase I observations, it is assumed that average extraction rates per well may be up to 3 gallons per minute (gpm). The Phase II design estimates a combined total recirculation rate (both extraction and injection) of 21 gpm and 12 gpm within the northern and southeastern areas, respectively. Where achievable, injection and extraction rates will be increased to maximize the total quantity of groundwater extracted and injected within the capabilities of both treatment areas (40 gpm each). Based on previous testing at the site and the common ratios of injection well capacity relative to injection wells, it is estimated

that injection rates may vary between 0.5 to 3 gpm per well. Injection wells may be operated at higher flow rates, depending on the nature of the soil formation and ability to receive fluids. Over the course of operation, the Phase II design entails initiation of injection activities within the northern end of Site 114, followed by gradual southward shifts in operating wells. Based on the model flow rates, these have been conceptualized as three, 8-week cycles. Similarly, injection activities in the southeastern area will gradually shift further east during the Phase II operation. Individual cycles may be extended in length (e.g., to 12 or 16 weeks) based on performance and observed reactive zone development.

The treatment of groundwater used for reinjection will be sufficient to achieve either 95% reduction of influent levels (e.g., primarily for Cr and Cr[VI]) or concentrations below the applicable Ground Water Quality Standard (GWQS) values (e.g., for Cr, Cr[VI], and other compounds with historical detections) in the effluent of the water treatment plant, whichever is less stringent. A groundwater Classification Exception Area (CEA) was established on 7 June 2018, which allows for the discharge of water containing Cr, Cr(VI), metals, volatile organic compounds (VOCs), and semi-volatile organic compounds (SVOCs) which may not be treated to levels below the GWQS by the water treatment plant prior to re-injection. The compounds other than Cr and Cr(VI) that were historically detected above the respective GWQS in the shallow, intermediate, and deep water-bearing zones are listed in the table below. Groundwater generated from the shallow water-bearing zone during soil excavation dewatering will be combined with groundwater extracted from the intermediate and deep water-bearing zones and treated with the water treatment plant. The CEA comprises the entirety of the project area (Block 21501, Lots 16 through 20), and extends to a depth of 100 feet below ground surface.

## II. SYSTEM OPERATION AND MONITORING

The area of discharge shall be monitored for evidence of malfunction. Said evidence shall include, but is not limited to: injection solution observation at land surface, wet areas, ponding, odors, and elevated photoionization detector (PID) readings in the nearby work area or building. If encountered, appropriate controls and system modification will be implemented.

The discharge shall not cause any of the following negative impacts: adverse impact on the behavior of free product or the plume; adverse impacts to a water supply well or have a long term adverse impact on ground water quality; create an unpermitted discharge to any surface water of the State or violation of Surface Water Quality Standards; create a persistent standing, ponded or surface-flowing fluid condition; or cause adverse vapor intrusion to occur.

Pursuant to N.J.A.C. 7:14A-6.2(a)5 and 11, if free product in ground water, vapors or odors in any building, or any malfunction resulting in a potential impact to a receptor are detected and are a result of the discharge authorized by this approval, the discharger will immediately: (1) cease the discharge or make necessary adjustments to the discharge rate or system operation; and (2) repair or mitigate any negative impacts.

After completion of the discharge, the property returned to its previous condition, or as agreed to with property owner if the permittee is not the property owner. All UIC-Class V injection wells shall be properly abandoned in accordance with N.J.A.C. 7:14A-8.16(d)1 as applicable. The permittee will comply with any applicable provisions of the Additional Conditions Applicable to Class I, II, III and V UIC Permits of the NJPDES regulations, N.J.A.C. 7:14A-8.9, et seq. when UIC-Class V injection well units (i.e., the injection points) are used.

## III. GROUND WATER MONITORING REQUIREMENTS

The Permittee shall perform the following ground water sampling as was specified in the DGW proposal (including all addendums and modifications) for the purpose of complying with this Discharge to Ground Water Permit-By-Rule authorization.

Baseline Sampling, before injection:

Prior to the startup of Phase II operations, but following the installation of the remediation well network and new monitoring well locations, samples will be collected for baseline analysis to establish the starting conditions for IRM treatment performance review. In accordance with the attached Table 1, baseline samples will be collected for TAL metals (total and dissolved); Cr(VI) (total and dissolved); key geochemical parameters (sulfate/sulfide and methane); total organic carbon (TOC), field parameters (pH, specific conductivity, dissolved oxygen [DO], oxidation-reduction potential [ORP], turbidity, and temperature); and depth to groundwater.

Baseline samples will be collected using the low-flow sampling method. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be

gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 micrometer (μm) filters in the field.

Operational and Treatment Monitoring, during the injections:

The operational monitoring program will be used to assess ongoing remedial system performance in support of guiding potential modifications to injection and extraction flow rates, recirculation well balancing, carbon dosing and timing, and to pre-emptively guide potential biofouling management and well redevelopment.

Operational monitoring will be performed at variable frequencies (weekly, biweekly, or monthly), as necessary, over the course of operation pursuant to Table 1. Measurements may be periodically performed more frequently than specified in Table 1 to support potential troubleshooting activities over the course of operation. Given the adaptive nature of the recirculation program and the sequencing of different groupings of injection and extraction wells during operation, it is anticipated that the operational sampling frequency of existing monitoring wells will be adapted over time. As an example, monitoring wells located within the northernmost area of Site 114 are most relevant for operational monitoring during the first step of recirculation activities. Following this initial period and the transition to more southerly injection wells, the frequency and parameter list of the initial monitoring locations may be reduced to maintain remedial efficiency, as applicable, subject to NJDEP approval. For the operational monitoring, analytical data and field parameter measurements for extracted and treated groundwater will be collected at operating extraction wells from sampling ports located at the wellheads or at the influent to the water treatment system.

Overall Phase II remedial performance will be documented via ongoing treatment monitoring during the 12-month IRM program. Sampling parameters will be collected to verify organic carbon distribution, assess the development of reduced geochemical groundwater conditions within the subsurface, and confirm corresponding declines in total Cr and Cr(VI). Evaluation of these parameters will confirm development of the subsurface reactive zone and will be used to guide carbon substrate dosing strength and frequency. This will enable treatment optimization and confirmation prior to transitioning the operating recirculation wells to subsequent steps. A summary of the analytical and field parameter measurements for treatment sampling is provided in Table 1.

Similar to the operational monitoring specifications, treatment monitoring parameters will be collected at specified frequency based on the relevance of a given parameter to operation and optimization activities. TOC and field parameter sampling is proposed most frequently (biweekly to monthly) to effectively gauge propagation of both carbon substrate and geochemical influence within the subsurface. Total Cr and Cr(VI) and select geochemical parameters (ferrous [dissolved] iron, dissolved manganese, sulfate) will be collected monthly to enable the collection of at least one to two samples between recirculation well steps. Methane sampling is also proposed, albeit less

frequently, to confirm the overall extent of reduced groundwater conditions. Similar to the sampling frequency considerations presented for the operational monitoring program, treatment monitoring parameters will be collected at a specified frequency based on the relevance of a given parameter to operation and optimization activities.

Treatment monitoring samples will be collected using the low-flow sampling method and select wells may be sampled at 5-foot intervals. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 μm filters in the field.

Post Treatment Sampling, after completion of injections:

Following the 12-month Phase II operational program, post-treatment monitoring will be used to document overall Cr treatment performance, confirm the residual reactive zone reduction capacity (via residual TOC and reduced geochemistry species), and develop an appropriate data set to demonstrate ongoing natural attenuation of any residual total Cr and Cr(VI). Post-treatment sampling will be performed in accordance with Table 1.

Treatment monitoring samples will be collected using the low-flow sampling method and select screen locations with wells will be sampled at 5-foot intervals. Purge water generated during sampling will be temporarily stored and then transferred to the groundwater treatment system – or containerized and disposed of off-site, as appropriate. Prior to the start of purging, depth to water will be gauged at each well location. Following purging, field parameter measurements will be recorded. Samples collected for dissolved metal analyses will be filtered using 0.45 μm filters in the field.

Post-treatment sampling activities will be performed on a quarterly basis over a total duration of two years.

Pursuant to the Tech Regs, the Permittee shall measure ground water elevations at all sampled wells during each sampling event and shall construct ground water flow maps with the water elevation data to document the direction of ground water flow. Any non-aqueous phase liquid (NAPL) observed, including sheen, shall be documented and the NJDEP shall be notified. The Permittee shall check for both light non-aqueous phase liquid (LNAPL) and dense non-aqueous phase liquid (DNAPL). If NAPL is identified in thicknesses greater than 0.01 feet in wells planned for injection use during baseline gauging or subsequent routine performance monitoring activities, these wells will be operated first as extraction wells to facilitate NAPL recovery and removal. NAPL will be recovered and modifications will be made to allow oil separation prior to transfer to the water treatment system. Prior to converting these wells for injection use, extraction will be discontinued to allow static gauging for NAPL reoccurrence. If NAPL is not observed with thicknesses in excess of 0.01 feet for two consecutive gauging events, and the NJDEP concurs, then NAPL will be considered eliminated or recovered to the extent practicable and wells will be deemed acceptable for injection use. Alternatively, if NAPL is identified in

excess of 0.01 feet in thickness but is considered no longer recoverable (or immobile), and the NJDEP concurs, the NAPL will be considered recovered to the extent practicable and wells may also be deemed acceptable for injection use.

All sampling shall be performed as proposed and consistent with the methods specified in the most current edition of the Department's Field Sampling Procedures Manual. All samples shall be analyzed by a New Jersey Certified Laboratory certified for the methods being used to analyze groundwater samples. Analytical method MDLs shall be less than or equal to the ground water quality standards (N.J.A.C. 7:9C-1.7). Parameters determined in the field (pH, specific conductance, dissolved oxygen, temperature) are to be measured by a certified contractor or laboratory.

Comparison to the VI screening levels is necessary in order to monitor whether or not the discharge activities have the potential to cause VI issues within any nearby structures by means of adversely impacting the behavior of the ground-water contaminants (e.g., unexpected contaminant movement). If there are any exceedances of the VI screening levels caused by the authorized discharge, a VI evaluation shall be conducted of any potentially impacted structures.

Compliance with N.J.A.C. 7:26E-5.7(b) requires that the Permittee satisfy the post-injection ground water monitoring requirements that are set forth in this letter before applying for any Remedial Action Permit for Ground Water. If a Remedial Action Permit application is submitted before the required ground water sampling has been completed, the application will be denied.

Additionally, contingency compliance ground water sampling is required if ground water sampling results indicate that GWQS have been contravened because of the authorized discharge (e.g., the GWQS for sulfate is exceeded as a result of calcium polysulfide injection, or the GWQS for iron is exceeded as a result of FerroBlack®-H injection), or that ground water quality has not returned to baseline conditions (when baseline concentrations are greater than GWQS) in the expected timeframe. Ground water sampling must continue until it can be demonstrated that the GWQS have been met or until the ground water quality has returned to baseline conditions. To demonstrate either of these conditions, a minimum of two consecutive ground water sampling events spaced far enough apart to account for seasonal fluctuations, must be conducted.

Furthermore, if the Permittee is planning to apply for a Ground Water Remedial Action Permit for Natural Attenuation in the future, and exceedances of the GWQS that are due to the discharge remain, those exceedances must be treated similarly to any other site related contaminants (i.e., a sufficient number of samples is required and a decreasing concentration trend must be evident) consistent with the Department's Remedial Action Permits for Ground Water Guidance.

## IV. REPORTING REQUIREMENTS AND INFORMATION SUBMITTALS

Details of the supplemental pre-design testing, well and system installation, system operation, and performance monitoring results associated with the IRM Phase II program will be documented as part of a quarterly technical status reports submitted to the NJDEP. These quarterly status reports will include succinct, high-level summaries of activities performed, data collected, adaptive steps taken to modify or optimize Phase II treatment, and an overview of activities planned for the subsequent quarter.

Succinct performance summary results will be submitted as part of quarterly status reports. All information, including a complete summary of the work performed under the PBR, a complete set of the data collected, a summary of data trends, an evaluation and interpretation of the data, and conclusions reached (as well as the QA/QC package specified at N.J.A.C. 7:26E-2.1(a)15) shall be submitted as part of the completion report within 6 months following cessation of active Phase II operation. All information shall be submitted to:

NEW JERSEY DEPARTMENT OF ENVIRONMENTAL PROTECTION
BUREAU OF CASE ASSIGNMENT & INITIAL NOTICE
MAILCODE 401-05H
P.O. BOX 420
TRENTON, NJ 08625-0420
ATTN: COPR

Consistent with N.J.A.C. 7:14A-2.11(a) and 6.2(a)14, within 90 days after initiation of the discharge, notify the Department of the "start date" of the discharge. To report this date, send an email to Wayne.Howitz@dep.nj.gov stating the start date of the discharge.

Consistent with N.J.A.C. 7:14A-2.11(a) and 6.2(a)14, any malfunctions or non-compliance should be reported by fax or telephone within 24 hours to Wayne Howitz of the Site Remediation Program at (609) 984-2905, and in writing within 7 days to the above address using the subject line "DGW Permit-by-Rule Compliance Report - COPR." Written submissions must include the facility name and PI Number. Failure to report this information is a violation of N.J.A.C. 7:14A and the permit-by-rule.

If you have any questions or concerns, please contact Wayne C. Howitz of the Site Remediation Program at (609) 984-2905.

Sincerely,

Wayne C. Howitz, Assistant Director
Remediation Oversight Element

| Subject: | [EXTERNAL] Re: PPG -> GW-IRM-019 Permit-by-Rule Modification |
| Attachments: | 2021-01-19_PBR_Modification_DNAPL_Approach_DS.pdf |

Good afternoon,

The New Jersey Department of Environmental Protection (NJDEP) hereby approves the proposed modification (memo from AECOM dated 19 January 2021) of the Groundwater Interim Remedial Measure (IRM) Phase II Design Permit-by-Rule (PBR) that was approved by the NJDEP on 9 May 2019 for the Garfield Avenue Group Sites located in Jersey City, New Jersey.

The work shall be conducted in accordance with the aforementioned proposal. In order to commence the Phase II IRM program in the southeastern area of Site 114, the Phase II IRM PBR is modified to allow the following:

- DNAPL in existing injection, groundwater extraction, and monitoring wells will be pumped out from the wells to the extent possible, followed by commencement of the Phase II IRM reagent injections and groundwater extraction in select wells. One or more groundwater extraction wells may be converted to reagent injection wells to treat groundwater and will be determined based on operation and treatment monitoring.
- Injection wells will be monitored for DNAPL accumulation by observing injection pressures and flow rates. If DNAPL accumulation is suspected, the reagent injection at those wells will be temporarily stopped and DNAPL will be removed. The wells will then be returned to service.
- The Phase II IRM monitoring wells will be periodically gauged for DNAPL. DNAPL will be pumped out from these monitoring wells to the extent possible and as needed in order to continue monitoring activities. The frequency of the gauging and removal events in monitoring wells will be determined based on findings during the treatment period.

This email will serve as the official approval of the PBR modification. A copy of the proposal and this email exchange will be uploaded into NJEMS to document the Department's approval.

Thanks for your assistance with this. And feel free to forward this email to any interested parties.

David

**Subject: Discharge to Groundwater Permit-By-Rule Authorization Request**
**Garfield Avenue Group Sites, Groundwater Phase III Interim Remedial Measure**
**Jersey City, Hudson County, New Jersey**

To Whom It May Concern:

AECOM, on behalf of PPG, has prepared this Phase III Groundwater Interim Remedial Measure (IRM) New Jersey Pollutant Discharge Elimination System (NJPDES) Discharge to Groundwater (DGW) Permit-By-Rule (PBR) Authorization Request for portions of the Garfield Avenue (GA) Group Sites, part of the Hudson County Chromate (HCC) Sites in Jersey City, Hudson County, New Jersey (Project Area). The Project Area is shown on **Figure 1**.

Groundwater IRMs are being implemented on HCC Site 114 to actively treat groundwater impacted with total chromium (Cr) and hexavalent chromium ($Cr^{+6}$) in the shallow, intermediate, and deep water-bearing zones. The Phase I IRM was implemented between July 2017 and March 2020 under a PBR authorization issued by the New Jersey Department of Environmental Protection (NJDEP) (NJDEP, 2017). Completion of the Phase I IRM program is being followed by post-treatment performance monitoring through early 2022. As confirmed during treatment monitoring and post-treatment monitoring, the Phase I IRM has reduced Cr and $Cr^{+6}$ concentrations within the Site 114 area and is expected to reduce future mass flux from the treated areas and potential mass discharge outside of Site 114. The Phase II IRM system has been installed and full-scale operation began in October 2020 under its own PBR authorization (NJDEP, 2019). Phase II IRM operation is ongoing and will be followed by up to two years of post-treatment monitoring. A third IRM phase (Phase III) is planned to treat groundwater impacted with Cr, $Cr^{+6}$, and other select target constituents identified as emanating from Site 114 in areas beyond the horizontal and vertical limits of the Phase I and Phase II IRM areas, and is the subject of this PBR Authorization Request.

The Phase III IRM area includes select portions of water-bearing zones within the following areas outside of Site 114: Carteret Avenue; select areas within HCC Sites 132, 137 and 143; Halladay Street North; intersection of Carteret Avenue and Pacific Avenue; in the vicinity of the 101 Pacific Avenue property; Forrest Street; and Site 199. The Phase III IRM also includes targeted treatment in strategic areas within the lower portion of the deep water-bearing zone on Site 114. In addition, a limited area within the shallow water-bearing zone on Site 199 is being targeted for treatment of

tetrachloroethene (PCE). **Table 1** summarizes the Sites and properties, addresses and NJDEP Site Remediation Program (SRP) Program Interest (PI) numbers (where applicable) of the areas included in the Phase III IRM.

The three IRMs use a combination of demonstrated active remediation technologies, including *in situ* anaerobic bioprecipitation (ISAB) and *in situ* chemical reduction (ISCR), to achieve the IRM objectives. Post-treatment monitoring data from Phase I IRM show that the IRM decreased groundwater Cr and $Cr^{+6}$ concentrations by three to four orders of magnitude across most of the treatment area, with $Cr^{+6}$ concentrations below the analytical detection limits at most monitoring locations and reductions in the lateral extent of the groundwater plume within the treatment area (Arcadis, 2021). Lessons learned from the Phase I program were adopted as part of the Phase II design, and current treatment monitoring data from the Phase II IRM indicate the development of a reactive zone and decreases in groundwater Cr and $Cr^{+6}$ concentrations in the treatment areas (AECOM, 2021a). Lessons learned from the Phase I and Phase II IRMs will be applied to the Phase III IRM and it is expected that the treatment efficacy achieved by the Phase I and Phase II IRMs will also be achieved by the Phase III IRM.

The remainder of this letter provides a summary of the Project Area geology and hydrogeology, IRM objectives, target treatment areas, description of the Phase III implementation approach, groundwater monitoring program, reporting, regulatory and permitting considerations, and references. The Phase III IRM PBR is intended to be flexible and adaptive and has been streamlined to include the lessons learned during implementation of the Phase I and Phase II IRMs.

**Project Area Geology and Hydrogeology**

The Project Area is located on miscellaneous fill material that was used to reclaim the salt marsh for the construction of this portion of Jersey City. Native materials beneath the fill include an organic meadow mat layer, unconsolidated deposits of glacial origin, and bedrock. The geology within the Project Area consists of:

- Fill (*the shallow zone*), consisting of:
    - Non-native fill materials in areas where soil remediation is not needed or has not yet been implemented, and
    - Clean fill (unamended or amended with the FerroBlack®-H reductant) where the previously existing non-native fill materials and subsurface structures were excavated to remove sources of chromium (Cr);
- Underlying the fill, a discontinuous layer of estuarine organic-rich deposits (*meadow mat*);
- Underlying the meadow mat, or directly below the fill where the meadow mat is absent, native soils consisting of sands, silty sands, silts, and clays (*the intermediate zone*) generally separated from the underlying deep zone by a layer of interbedded lower permeability silts, clayey silts, silty sands, and clays (*the transition zone, part of the intermediate zone);*

- Underlying the intermediate zone, sands with lenses of silt, clay, and gravel underlain by the basal facies of the Rahway Till (*the deep zone, includes the basal till and overlying sands);* and

- Underlying the overburden, bedrock of the Lockatong and Stockton Formations with a diabase sill intruding into the Lockatong formation along the western edge of the Project Area (*bedrock zone*).

Groundwater in the Project Area occurs within distinct hydrostratigraphic water-bearing zones (units), as follows:

- *Shallow Water-Bearing Zone*: includes groundwater present in the fill from the water table to the top of the meadow mat. Where the fill was excavated during soil remediation, the backfill is a more uniform dense-graded aggregate (DGA) material or DGA amended with FerroBlack®-H. In the northeastern corner of Site 114, beyond Forrest Street, a native sandy unit underlies the fill above the intermediate water-bearing zone deposits.

- *Intermediate Water-Bearing Zone:* includes groundwater present in the meadow mat, the underlying sand unit, and the transition zone. Where present, the meadow mat is the transition zone between the shallow and intermediate water-bearing zones and generally limits vertical groundwater movement between these zones. Where meadow mat is absent, the shallow and intermediate water-bearing zones are in direct contact. Where present, the transition zone behaves like an aquitard due to its lower permeability. The intermediate water-bearing zone pinches out against the rising bedrock surface west of the Project Area (beyond Garfield Avenue).

- *Deep Water-Bearing Zone*: north of Carteret Avenue, the deep zone consists primarily of sand and gravel with lenses of clay or silt underlain by basal till. South of Carteret Avenue, the deep zone becomes more difficult to differentiate from the intermediate zone as both zones grade into thicker sequences of lower conductivity materials such as silts, clays, and fine sands with silt and clay. The deep water-bearing zone pinches out against the rising bedrock surface on the western margin of the Project Area near Garfield Avenue.

- *Bedrock Water-Bearing Zone:* consists primarily of the Lockatong Formation, with the Palisades Sill (diabase) along the western edge of the Project Area and a section of the Stockton Formation in the eastern portion of Site 114. Groundwater flow within the bedrock occurs only within interconnected bedrock fractures, bedding planes, cracks, and voids. Yields from bedrock wells in the Project Area are low (0.02 to 0.05 gallons per minute [gpm]). Groundwater flow in bedrock is a small fraction of the total groundwater flux through the Project Area.

**Phase III IRM Objectives**

The objectives of the Phase III IRM program are to:

- Actively treat groundwater $Cr^{+6}$ concentrations greater than 1,000 micrograms per liter (µg/L) within targeted water-bearing zones where practicable using a combination of one or more ISAB and/or ISCR alternatives. Also, treat or reduce concentrations of other constituents of concern (COCs) in groundwater[1];

- Inject electron donors to create and support ISAB and/or injections of chemical reductant to support ISCR in the target shallow, intermediate, and deep water-bearing zones;

- Inject FerroBlack®-H to establish *in situ* reactive zones (IRZ) to create and support ISCR in target areas and water-bearing zones; and

- Document post-treatment trends in groundwater quality with respect to total Cr and other COCs, showing continuing attenuation/reduction toward the Class II-A Groundwater Quality Standards (GWQS).

**Target Treatment Areas**

The horizontal and vertical extent of the Project Area where Cr is present in groundwater at concentrations greater than 1,000 µg/L in the shallow, intermediate, and deep water-bearing zones was delineated by the groundwater Remedial Investigation (RI) (AECOM, 2021a). In defining the active remediation target treatment areas, it was assumed that Cr concentrations within the 1,000 µg/L Cr isopleths consist entirely of $Cr^{+6}$. Active groundwater treatment for a portion of these areas has already been completed or is ongoing via implementation of the Phase I and Phase II IRMs. Treatment of the remaining areas will be accomplished via implementation of the Phase III IRM. Based on this information, **Figure 2-1, Figure 2-2,** and **Figure 2-3** show the target treatment areas for the Phase III IRM for the shallow, intermediate, and deep water-bearing zones, respectively. The depicted target treatment areas are approximate, have been developed using available data, and may be refined before commencement of active treatment as additional data are collected during installation of the Phase III IRM remediation wells and monitoring wells.

**Phase III IRM Approach**

As stated above, the three IRMs use a combination of demonstrated active remediation technologies, including ISAB and ISCR, to achieve the IRM objectives. Although biological and chemical treatment mechanisms differ, both treatment processes are designed to reductively precipitate and permanently fix/immobilize the $Cr^{+6}$ in the aquifer, reduce $Cr^{+6}$ concentrations in groundwater to achieve remediation goals, and support long-term treatment permanence.

***In situ Anerobic Bioprecipitation*** is an established biologically-mediated remedial technology for the treatment of metals (e.g., Cr) and other COCs in groundwater. This technology uses continuous or periodic delivery of degradable organic carbon substrates, such as molasses or emulsified vegetable oil (EVO), into the contaminated groundwater system to stimulate the native microorganisms and promote the development of an IRZ. Within the IRZ, fermentation of the organic carbon substrate promotes development of iron- and sulfate-reducing groundwater conditions that are favorable for the

[1] The concentrations of non-Cr COCs within the active treatment areas are lower compared to Cr and are not the primary targets of the active remedy. Several of the non-Cr COCs will be treated using the selected active remedies (e.g., *in situ* via ISAB or ISCR), specifically PCE on Site 199.

reduction of $Cr^{+6}$. Under these conditions, $Cr^{+6}$ is reduced to $Cr^{+3}$ through reactions with multiple biologically-generated reductants or via direct anaerobic respiration with $Cr^{+6}$ serving as the terminal electron acceptor. The reduction of $Cr^{+6}$ to $Cr^{+3}$ provides three benefits from a treatment perspective:

- $Cr^{+3}$ is less toxic than $Cr^{+6}$ and, therefore, has higher permissible environmental concentrations;
- $Cr^{+3}$ is less soluble than $Cr^{+6}$ under Project Area groundwater conditions and forms a precipitate that is immobilized in the form of a hydroxide mineral that can be incorporated in a matrix of carbonate, sulfide, and other precipitates generated during the treatment process; and
- Insoluble $Cr^{+3}$ phases are resistant to re-oxidation to $Cr^{+6}$ phases under the soil and groundwater conditions at the Project Area.

The above benefits, combined with the pH-neutralizing effects of organic carbon fermentation, and the capability of the ISAB process to establish a reactive zone with sustained biological and abiotic reduction capacity, make $Cr^{+6}$ treatment via ISAB a suitable groundwater remedial technology for the Project Area. A pilot test was completed in 2014 within the shallow and intermediate water-bearing zones of the former Phase IRM I test area on Site 114 to test the effectiveness of an ISAB remedy for $Cr^{+6}$-contaminated groundwater. The performance monitoring results show that treatment of $Cr^{+6}$ impacts was achieved in groundwater and soil in the test area, with the treatment goals of 90% reduction of $Cr^{+6}$ in groundwater, and the target concentration of 20 milligrams per kilogram (mg/kg) of $Cr^{+6}$ in soil, being met. Based on the pilot test results, ISAB was selected for the Phase I and II IRM programs. Performance monitoring data from the Phase I IRM through the fourth quarter of 2020 show that Cr and $Cr^{+6}$ concentrations were reduced by three and four orders of magnitude (compared to baseline conditions) in the majority of the Phase I treatment area, with limited exceptions (Arcadis, 2021). In the Phase II IRM area, breakthrough with respect to total organic carbon (TOC) concentrations present in treatment areas with greater than baseline TOC concentrations, and decreases in Cr and $Cr^{+6}$ concentrations were observed in several monitoring wells during treatment monitoring and is expected to progress further as the remainder of the injection program is completed (AECOM, 2021a).

***In Situ Chemical Reduction*** is a direct abiotic chemical reduction treatment that is implemented by introducing a reductant to chemically reduce $Cr^{+6}$ to less soluble $Cr^{+3}$, which in turn geochemically binds onto soil surfaces in the target groundwater treatment zone. This is achieved by the delivery of the chemical reductant into the subsurface, which facilitates abiotic Cr removal in the aqueous phase via conversion of $Cr^{+6}$ to $Cr^{+3}$ and subsequent precipitation as either chromium hydroxide ($Cr[OH]_3$) or as iron-Cr hydroxide complexes. An ISCR pilot test was conducted in 2016 on Site 114 to evaluate the applicability of abiotic treatment for $Cr^{+6}$ in groundwater and saturated soil. During the ISCR pilot test, two chemical reductants, FerroBlack®-H and calcium polysulfide (CPS), were tested to assess the viability of ISCR at the Site. The pilot test performance monitoring results demonstrated that $Cr^{+6}$ and total Cr concentrations were reduced by greater than 90% and 75%, respectively, when compared to the baseline concentrations. Overall, pilot testing showed that ISCR is effective for $Cr^{+6}$ treatment and is included in the selected active remedy to complement ISAB. This technology provides reagent flexibility and can be applied alone or in combination with ISAB to optimize the remediation strategy.

The ISAB/ISCR approach to the Phase III IRM will vary across the treatment areas depending on soil heterogeneity, soil and structure geotechnical sensitivity, distribution of $Cr^{+6}$ concentrations within the targeted water-bearing zones, and location of existing structures (buildings, light rail,

etc.). *In situ* reagent injections and FerroBlack®-H IRZs will be used to treat $Cr^{+6}$ in groundwater and will be tailored to each of the shallow, intermediate, and deep treatment zones.

**Table 2** includes the proposed reagents (molasses, EVO, CPS and FerroBlack®-H) and the calculated target injection volumes for each of the Phase III IRM treatment areas and water-bearing zones. **Table 3** shows the approximate pore volumes proposed for treatment by target areas with molasses, EVO and/or CPS. **Appendix A** includes Safety Data Sheets for these reagents.

### *In Situ Injections*

*In situ* injections will be performed using a permanent well network screened at target depths and may be supplemented with the use of direct push injections, as needed. The locations of the proposed injection wells in the shallow, intermediate, and deep water-bearing zones are shown in **Figure 3-1, Figure 3-2, and Figure 3-3**, respectively. Note that the number and location of proposed injection wells are approximate and subject to change based on Phase III IRM performance and observed monitoring results.

Injections will be implemented in phases and will begin along the downgradient edge of each target area to establish a reactive zone along the boundary (edge) prior to, and potentially during, injections in upgradient areas. Injection flow rates at individual wells may vary from 0 to 1.5 gpm based on experience during the Phase I and Phase II IRMs. Optimum injection pressures will be field determined but are not expected to exceed 10 pounds per square inch (psi) in the shallow water-bearing zone, 20 psi in the intermediate water-bearing zone, and 25 psi in the deep water-bearing zone.

A well-point dewatering system may be installed and screened in the intermediate or shallow water-bearing zones in and around Carteret Avenue prior to commencing injection activities. If used, the dewatering system will be operated for approximately one month prior to commencing injection activities to depress the water table and reduce pore pressure, with the goal of optimizing the injection period and preventing hydraulic mounding. The dewatering system may continue to be operated during injection activities to manage hydraulic mounding, if needed. Once injected reagents are detected within the dewatering points, the dewatering system operation will be discontinued to prevent removal of reagent from the treatment zone. Groundwater removed via the dewatering system will be directed to the existing onsite groundwater treatment plant.

### *Ferro Black®-H Reactive Zones*

In areas planned for $Cr^{+6}$ treatment using FerroBlack®-H, the reagent will be delivered into the target zones to establish a reducing environment within the zone of influence of the injected material. FerroBlack®-H is a proprietary reagent of Redox Solutions, LLC, and is a reductive, colloidal suspension of 1-2% by weight (wt.) soluble sulfides and 7-8% by wt. insoluble iron sulfides (FeS). The effectiveness of this chemical reductant was demonstrated in laboratory, bench-scale, and pilot-scale testing, and through its use as a backfill amendment across the Project Area over the last decade (AECOM, 2021c).

The reagent will precipitate $Cr^{+6}$ out of the aqueous phase as iron-chromium hydroxide complexes, thereby reducing the concentration of dissolved-phase Cr. The soluble sulfides component serves as a short-term source of sulfides (electron donor) to promote the reduction of $Cr^{+6}$ to $Cr^{+3}$, while the minimally soluble FeS particles act as a long-term source of reductant. The reduction of $Cr^{+6}$ to the

less toxic, less mobile $Cr^{+3}$ precipitates by FerroBlack®-H occurs through one or more geochemical processes, whereby:

- The soluble sulfides component of the FerroBlack®-H reacts rapidly with aqueous $Cr^{+6}$, providing a readily available source of electron donor (i.e., dissolved sulfides) resulting in its reduction to $Cr^{+3}$ and the formation of an iron-chromium precipitate; and

- The insoluble phase of FerroBlack®-H, mainly comprised of minimally soluble FeS particles, provides a slow-release long-term source of both iron and sulfur species to promote the continued reduction of $Cr^{+6}$ to $Cr^{+3}$, through a combination of dissolution, surface adsorption, and co-precipitation reactions. The reduction of $Cr^{+6}$ occurs at the FeS particles' surface, and results in the formation of $Cr^{+3}$-$Fe^{+3}$ hydroxides or oxyhydroxide (e.g., $Cr^{x}Fe^{1-x})(OH)_3$ or $Cr^{x}Fe^{1-x}OOH$) at pH conditions greater than 4 standard units (AECOM, 2021c). The mineral matrix of the FeS will continue to provide a slow-release, long-term source of reductant.

FerroBlack®-H reactive zones are being considered for three target areas: (1) in the southwestern quadrant of Site 114 within the lower portion of the deep water-bearing zone below the transition zone and beneath the vertical limits of the Phase I IRM, but above the top of the basal till; (2) east of the intersection of Carteret and Pacific Avenues in the intermediate water-bearing zone; and (3) potentially on and/or immediately adjacent to Site 199 in the intermediate water-bearing zone. Each of the three Area 1 FerroBlack®-H reactive zones are anticipated to be approximately 250 feet in length perpendicular to the local groundwater flow direction, up to 15 feet in vertical thickness and range up to 20 feet in horizontal thickness based on the total volume of FerroBlack®-H to be emplaced in each reactive zone as depicted in Figure 3-3. The focal area of the FerroBlack®-H reactive zone in Area 2 east of Pacific Avenue is anticipated to be 180 feet in length in a line perpendicular to the local groundwater flow direction, approximately 40 feet in vertical thickness and range up to 20 feet in horizontal thickness. Additional contingency length beyond the target 180-feet is contemplated in Figure 3-2. The Area 3 FerroBlack®-H reactive zone along the boundary of Site 199 and Site 114 is anticipated to be approximately 135 feet in length, up to 30 feet in vertical thickness and range up to 15 feet in horizontal thickness as depicted in Figure 3-2. The ultimate location and geometry of each reactive zone will be finalized during the design and ultimately during FerroBlack®-H emplacement and will consider factors such as: utilities, access to non-PPG owned properties, structural stabilization of adjacent facilities, properties and structures, and proximity to the New Jersey (NJ) Transit Light Rail (on Site 199). The emplacement of the FerroBlack®-H reactive zone near the boundary of Site 114 and Site 199 is conceptual and is being contemplated to address potential future mass flux in groundwater from green-gray mud remaining under the light rail on Site 199. A geotechnical evaluation is underway to determine the technical practicability of establishing a FerroBlack®-H reactive zone near the boundary of Site 114 and Site 199 without disturbing the adjacent light rail and associated retaining wall structure. The reactive zone east of the intersection of Carteret and Pacific Avenues is designed to address the downgradient edge of Cr impacts for areas along Halladay Street that are not readily accessible for *in situ* injections. All final locations are subject to access.

In areas planned for FerroBlack®-H emplacement, the reagent will be delivered into the target treatment zones via a series of soil borings in a line generally perpendicular to the direction of groundwater flow. The lateral spacing of the soil borings will allow for overlapping radii of influence. Final depth intervals for the target treatment zones will be determined in the field based on observations made during installation of the soil borings that will serve as the reagent delivery points.

Once emplaced, the FerroBlack®-H will establish a reducing environment within the zone of influence of the injected material. The protocols for reagent delivery will be finalized during the design.

**Groundwater Monitoring**

The groundwater monitoring program for the Phase III IRM has been developed to support ongoing evaluation of treatment effectiveness and support continuous adaptation and optimization of the program. Phase III IRM monitoring activities are proposed as part of four primary categories to support treatment assessment and performance optimization, including: 1) baseline sampling, 2) operational monitoring, 3) treatment monitoring, and 4) post-treatment monitoring. A combination of both new and existing monitoring wells will be incorporated as part of each of these four monitoring categories. The monitoring schedule is described in **Appendix B**, which includes a schedule of the monitoring phases, monitoring parameters, and frequency. Existing and proposed monitoring wells for the shallow, intermediate, and deep water-bearing zones are provided on **Figure 3-1, Figure 3-2,** and **Figure 3-3**, respectively. A list of existing and proposed monitoring wells to be utilized for injection monitoring and treatment monitoring are provided in **Table 4-1** and **Table 4-2**, respectively. A list of the proposed injection wells is provided in **Table 4-3**. Recent sampling data for Cr and PCE from the existing monitoring well network are presented in **Appendix C**.

The duration of the monitoring program in each category may vary across the water-bearing zones and treatment areas and will be dependent on when active treatment begins in each area and the treatment effectiveness in each zone. Monitoring parameters and frequencies may be adjusted to optimize the monitoring program and allow treatment effectiveness to be evaluated and transition from the IRM to next phase of active treatment (i.e., enhanced attenuation, as described further in the Groundwater Remedial Action Work Plan [AECOM, 2021c]). Monitoring of groundwater parameters (e.g., depth to water, geochemical parameters, TOC, COCs) will allow for identifying potential groundwater mounding, evaluating the development of the reactive zone, and evaluating treatment efficacy. During the injection phases, reagent injection pressures, flow rates, and volumes will be monitored and may be adjusted to prevent daylighting or breakout of reagent at the ground surface.

**Reporting**

Details of the well and system installation, system operation, and operation and treatment monitoring results associated with the Phase III IRM will be documented as part of quarterly technical status reports submitted to NJDEP. These quarterly status reports will include succinct, high-level summaries of activities performed, data collected and graphs depicting apparent trends, adaptive steps taken to modify or optimize Phase III treatment, and an overview of activities planned for the subsequent quarter.

**Schedule**

PPG will proceed with startup of the Phase III IRM program upon issuance of the PBR Authorization by NJDEP and installation of the necessary IRM infrastructure (e.g., wells, piping, mobile injection units, utilities). IRM infrastructure construction may be initiated prior to PBR authorization to expedite elements of the project schedule, as necessary. Additionally, start-up will occur in stages in the various target areas (e.g., Target Area 1 injections are anticipated to start up prior to Target Areas 2 and 3). In accordance with the monthly groundwater Gantt chart submittals, Phase III IRM remediation and monitoring well installation is anticipated to begin in early May 2021. Work in areas

planned for FerroBlack®-H treatment is anticipated to commence by July 2021 on Site 114 and be completed by end of September 2021. Work in the other areas planned for FerroBlack®-H treatment will be completed by December 31, 2021.

The Phase III IRM operation is anticipated to start in the fourth quarter of 2021 and last for a duration of up to approximately 15 months, followed by a post-treatment monitoring period of up to two years. While the active injection period is anticipated to be concluded within approximately 15 months of start-up, it is requested that the PBR be authorized for five years in the event post-treatment monitoring results indicate additional reagent injections are required to achieve the objectives. The total reagent volumes presented in **Table 2** include contingency volumes for additional injections, if required, such that the total reagent volumes injected under this PBR authorization do not exceed the volumes in **Table 2**. As-built layouts for the Phase III IRM system will be provided within the appropriate quarterly status reports.

**Regulatory and Permitting Considerations**

Because the Phase III IRM proposes injections to groundwater, an NJPDES DGW PBR Authorization Request is included herein. Pursuant to NJPDES rules (New Jersey Administrative Code [N.J.A.C.] 7:14A-7.5 and 8.5) and Technical Requirements for Site Remediation (N.J.A.C. 7:26E-5.6), this letter provides the PBR Authorization Request Form (**Appendix D**) and a description of the DGW activities. In addition, because the DGW PBR involves operation beyond 180 days, a 30-day public notice is required prior to the start of the groundwater discharge in accordance with 7:26E-5.6 (c)1-4. A draft public notice is provided as **Appendix D**. Proof of publication will be provided to NJDEP within 15 days after the notice is published.

Right of way permits for injection and monitoring well installations in city streets and sidewalks outside the Site 114 fence line will be obtained prior to installation. Additionally, the Temporary Access Permit (TAP) with New Jersey Transit will be updated before the installation of wells or implementation of FerroBlack®-H emplacement on Site 199.

PPG currently maintains a Water Allocation Permit (WAP) for the site (WAP190001) associated with the ongoing excavation dewatering efforts and Phase II IRM operations. The current WAP covers the PPG GA Group sites with an upper limit of total water from all diversion sources of 6 million gallons per month/50 million gallons per year. If the well-point dewatering system is implemented, operation of the proposed Phase III IRM dewatering system will be balanced with the operational needs of the existing Phase II IRM groundwater extraction system and the excavation dewatering extraction needs, such that the total water diversion will stay within the approved volumes of the current permit. The existing WAP will be updated with the required information for the Phase III IRM dewatering system, if implemented, and prior to commencement of water withdrawal activities.

**Notes:**

1. Block and lot numbers were sourced from the tax map of Jersey City (Sheet 215), last updated 12/2020, accessed at: http://hostedfiles.civilsolutions.biz/jerseycity/taxmaps/index.htm

COPR = chromite ore processing residue

Cr = chromium

MGP = manufactured gas plant

N/A = not applicable

SRP = Site Remediation Program

# Table 2
## Proposed Reagents and Injection Volumes
## Permit-By-Rule Authorization Request - Phase III Groundwater Interim Remedial Measures
## Garfield Avenue Group Sites
## PPG, Jersey City, New Jersey

| Treatment Type | Reagent[1] | Target Area (see Figures 2-1, 2-2, and 2-3) | Water-Bearing Zone (see Figures 2-1, 2-2, and 2-3) | Local Maximum Injection Solution Volume (Gallons) | Total Maximum Injection Solution Volume (Gallons) |
|---|---|---|---|---|---|
| ISAB | Molasses (0.05%) | Target Area 1 | Intermediate | 3,400,000 | 16,240,000 |
| | | | Deep | 120,000 | |
| | | | Contingency [3] | 3,520,000 | |
| | | Target Area 2 | Intermediate | 3,000,000 | |
| | | | Deep | 140,000 | |
| | | | Contingency [3] | 3,140,000 | |
| | | Target Area 3 | Shallow | 47,000 | |
| | | | Intermediate | 1,400,000 | |
| | | | Deep | 13,000 | |
| | | | Contingency [3] | 1,460,000 | |
| | Emulsified Vegetable Oil (EVO) (1.5%) | Target Area 1 | Intermediate | 580,000 | 2,752,000 |
| | | | Deep | 20,000 | |
| | | | Contingency [3] | 600,000 | |
| | | Target Area 2 | Intermediate | 510,000 | |
| | | | Deep | 24,000 | |
| | | | Contingency [3] | 534,000 | |
| | | Target Area 3 | Shallow | 9,000 | |
| | | | Intermediate | 230,000 | |
| | | | Deep | 3,000 | |
| | | | Contingency [3] | 242,000 | |
| ISCR | Calcium Polysulfide (CPS) (2.75%) | See Note 2. | | | |
| | FerroBlack®-H[4] | Target Area 1 | Deep | 168,000 | 796,000 |
| | | | Contingency [3] | 168,000 | |
| | | Target Area 2 | Intermediate | 162,000 | |
| | | | Contingency [3] | 162,000 | |
| | | Target Area 3 | Intermediate | 68,000 | |
| | | | Contingency [3] | 68,000 | |

**Notes:**

1. Percentages noted in this column represent the design reagent-to-potable water concentrations proposed to be injected into the respective water bearing zones.

2. A CPS solution may be substituted for up to 50% of the anticipated injection volume of molasses (i.e., 8,120,000 gallons), if baseline or treatment monitoring data suggest the presence of areas of elevated hexavalent chromium concentrations (i.e., greater than 1,000,000 µg/L).

3. Contingency volumes account for an additional 100% of the estimated required injection volumes and may be implemented based on Treatment Monitoring.

4. FerroBlack®-H volumes were calculated using treatability study values derived from previous bench-scale and pilot-scale tests conducted in 2016. Actual volumes will be determined at the time of installation.

ISAB = *in situ* anaerobic bioprecipitation

ISCR = *in situ* chemical reduction

µg/L = micrograms per liter

**Table 3**
**Approximate Mobile Pore Volumes for Treatment with Molasses/EVO/CPS**
**Permit-By-Rule Authorization Request - Phase III Groundwater Interim Remedial Measures**
**Garfield Avenue Group Sites**
**PPG, Jersey City, New Jersey**

| Water-Bearing Zone | Target Area 1 Mobile Pore Volume (Gallons) | Target Area 2 Mobile Pore Volume (Gallons) | Target Area 3 Mobile Pore Volume (Gallons) | Total Mobile Pore Volume (Gallons) |
|---|---|---|---|---|
| Shallow | 0 | 0 | 71,000 | **71,000** |
| Intermediate | 4,967,000 | 4,388,000 | 1,993,000 | **11,348,000** |
| Deep | 175,000 | 206,000 | 19,000 | **400,000** |
| **Combined** | **5,142,000** | **4,594,000** | **2,083,000** | **11,819,000** |

**Notes:**

1. Mobile pore volumes are estimated to be 15% of the total volume of soil and pore spaces. This assumption is consistant with the Phase I and Phase II Interim Remedial Measures.

EVO = Emulsified Vegitable Oil

CPS = Calcium Polysulfide

**Notes:**

1. A/B well designations denote locations where co-located wells with distinct well screen intervals are anticipated be required to span the vertical depth interval of the associated water-bearing zone. Necessity for co-located wells and final well screen intervals will be determined at the time of installation.

# Appendix A
# Safety Data Sheets

# Molasses

## 1. Identification of the substance and of the company

| | | |
|---|---|---|
| **1.1** | Product Identification: | Molasses |
| | Trade Name/Synonym(s): | Cane Molasses, Cane Syrup, Beet Molasses, Beet Syrup, Organic Molasses, High Test Molasses, High sugar Molasses, Desugarized Molasses, Blackstrap Molasses, Refiner's Syrup, Refiner's Molasses |
| | Description: | Molasses is a viscous by-product of the processing of sugar cane or sugar beets after which no more sugar can be economically crystallized by factory methods. Molasses is a dark sticky liquid. |
| **1.2** | **Pertinent uses identified for the mixture and uses not recommended** | |
| | Uses identified: | Animal feedstuffs; Fermentation; Industrial applications |
| | Uses not recommended: | Not intended for human consumption. |
| **1.3** | **Information regarding the supplier of the safety data sheet** | |
| | Company Identification: | Westway Feed Products LLC<br>14014 Park Drive, Suite 217<br>Tomball, TX 77377 |
| | Telephone Number: | (800) 654-9668 |
| | Fax Number: | (281) 351-4975 |
| **1.4** | Emergency Telephone: | (800) 654-9668 |

## 2. Identification of risks

**2.1 Hazard Classification:**

This product is does not meet the criteria for classification when reviewed according to the requirements of the Occupational Safety and Health Administration Hazard Communication Standard, 29 CFR 1910.1200.

**2.2 Elements of the label:**

| | |
|---|---|
| Hazard pictograms: |  |
| Signal word: | None |
| Hazard statements: | None |
| Precautionary statements: | Observe good industrial hygiene practices. |
| | Wash hands after handling. |
| | Store away from incompatible materials. |
| | Dispose of waste and residues in accordance with local authority requirements. |

**2.3 Hazards Not Otherwise Classified:** None known

## 3. Composition/information regarding the ingredients

Product contains the following hazardous substances:

| Chemical Name | CAS Number | % |
|---|---|---|
| Molasses | 68476-78-8 | 1 - 100 |
| Water | 7732-18-5 | 1 - 99 |

## 4. First aid measures

**4.1 Description of the first aid measures:**

| | | |
|---|---|---|
| | General recommendations: | Ensure that medical personnel are aware of the material(s) involved. |
| | Following inhalation: | Move to fresh air. |
| | Following skin contact: | Wash with water and soap. Remove contaminated clothing. |
| | Following eye contact: | Flush eyes for at least 15 minutes with clean water, lifting lower and upper eyelids occasionally. |
| | Following ingestion: | If swallowed, give several glasses of water to dilute. |
| | Self-protection of the first aider: | Ensure area is safe to enable first aid. |
| **4.2** | **Main symptoms and effects, both acute and delayed:** | |
| | Acute effects: | Direct contact with eyes may cause temporary irritation. |
| | Delayed effects: | None |
| **4.3** | **Indication of the possible need to immediately consult and physician and special treatments:** | |
| | Notes for the doctor: | See section 4.1 regarding the method of exposure |
| | Special treatment: | N/A |

## 5. Firefighting measures

| | | |
|---|---|---|
| **5.1** | **Fire extinguisher media:** | |
| | Suitable extinguisher media: | Water, carbon dioxide, foam or chemical powder can be used as a suitable extinguishing media. |
| | Unsuitable extinguisher media: | None known |
| **5.2** | **Special hazards arising from the substance or mixture:** | |
| | Hazardous combustion products: | Fermentation can yield carbon dioxide with possible traces of ethanol or volatile fatty acids (e.g. acetic, propionic, lactic, or butyric) and if exposed to a spark or flame may result in an explosion. These conditions should be avoided. Decomposition products released in a fire should be considered as harmful. |
| **5.3** | **Advice for firefighters:** | Wear self-contained breathing apparatus in case of large fires. |

## 6. Accidental release measures

| | | |
|---|---|---|
| **6.1** | **Personal precautions, protective devices and procedures in case of an emergency:** | |
| | For non-emergency personnel: | Ensure adequate ventilation. Spilled product may present slip hazard. Appropriate personal protective equipment is recommended. |
| | For emergency responders: | Keep unnecessary personnel away. Prevent the release from entering a waterway or sewer. |
| **6.2** | **Environmental precautions:** | Results in high Biological Oxygen Demand (BOD) and potential oxygen depletion of aquatic systems. |
| **6.3** | **Methods and materials for containment and for land reclamation:** | |
| | For containment: | Stop the source of the spill. Create diversionary structures to minimize the extent of the release. |
| | For cleaning up: | Use absorbent pads/materials to soak up small spills. A vacuum pump may be needed to recover larger spills. |
| | Other information: | Recover useable product. Absorb/wash down remaining spill and dispose of at an approved facility such as a municipal landfill or land application site in accordance with local procedures. |
| **6.4** | **Reference to other sections:** | |
| | Additional information: | N/A |

## 7. Handling and storage

# Molasses

| | | |
|---|---|---|
| **7.1** | **Precautions for safe handling:** | |
| | Measures/technical precautions: | Use with adequate ventilation. Wear appropriate personal protective equipment. Avoid direct contact with eyes. Molasses in containers can ferment spontaneously using oxygen and possibly create a hazardous atmosphere. If maintenance of tank requires entry by personnel, Confined Space Entry standards and procedures shall be observed and atmosphere testing must be performed prior to tank entry and thereafter daily. If welding is to be performed, tank should be ventilated to a safe atmosphere, (LEL < 10%) prior to entry. |
| | General hygiene: | Always observe good personal hygiene measures, such as hand washing after handling the materials and before eating, drinking, and/or smoking. Routinely wash work clothing and protective equipment to remove contaminants. |
| **7.2** | **Conditions for safe storage, including eventual incompatibility:** | |
| | Technical measures and storage conditions: | Store in a well-ventilated area or container. Store in suitable, labelled containers. Keep containers closed when not in use. Store below 120° F. |
| | Requirements for storage rooms and vessels: | Material can ferment if excessive moisture contamination is allowed. Ensure proper ventilation to prevent quality deterioration. |
| | Incompatible products: | None known |

| **8. Exposure controls/personal protection** | | | |
|---|---|---|---|
| **8.1** | **Occupational Exposure Limits:** | | |
| | None | | |
| | | | |
| **8.2** | **Exposure controls:** | Store below 120ºF. | |
| **8.2.1** | **Appropriate Engineering Controls:** | Provide general ventilation. | |
| **8.2.2** | **Personal protective equipment:** | | |
| | **Eye/Face Protection:** | | |
| | Suitable eye protection: | If contact is likely, safety glasses with side shields are recommended. | |
| | **Skin Protection:** | | |
| | Hand protection: | Wear suitable gloves and protective clothing. | |
| | Body protection: | Wear suitable gloves and protective clothing. | |
| | Other skin protection measures: | Wear suitable gloves and protective clothing. | |
| | Respiratory Protection: | In case of insufficient ventilation, wear suitable respiratory equipment. | |
| | Thermal Hazards: | Wear appropriate thermal protective clothing when necessary. | |
| **8.2.3** | **Environmental exposure controls:** | Ensure storage tanks/containers have adequate means to measure level of stored material to prevent overfilling. If stored near waterways or drains, ensure means of preventing spilled material from entering these areas. Ensure storage tanks/containers are regularly inspected to ensure integrity. | |

| **9. Physical and chemical properties** | |
|---|---|
| **9.1** | **Information regarding the basic physical and chemical properties** |

# Molasses

| | |
|---|---|
| Appearance/color: | Viscous, syrupy liquid – Brown to Black in color |
| Odor: | Sweet |
| Odor threshold: | No data |
| Flash point: | No data |
| Flammability: | No data |
| Upper/lower flammability/explosive limits: | No data |
| Vapor pressure: | No data |
| Relative density: | 1.0 – 1.5 g/ml (8.33 – 12.5 lbs/gal) |
| Solubility in water: | Soluble in water |
| Distribution/partition coefficient: | No data |
| Self-ignition temperature: | No data |
| Viscosity @ 20°C / 70°F: | 0-150,000 cps |
| pH: | 4-10 |
| Melting point: | No data |
| Freezing point: | < 0° F |
| Boiling point / range: | > 212° F |
| Evaporation rate: | No data |
| Decomposition temperature: | > 120º F |
| **9.2 Other information:** | None |

| **10. Stability and reactivity** | | |
|---|---|---|
| **10.1** | Reactivity: | Reacts with concentrated nitric acid. |
| **10.2** | Chemical stability: | Product is stable under normal conditions of use, storage, and transport. |
| **10.3** | Possibility of dangerous reactions: | Ferments when diluted with water. If diluted below 50%, fermentation may occur with large expansion in volume (addition of propionic or sulfuric acid to decrease pH to <4.5 will prevent fermentation). Care should be taken when adding sulfuric acid to prevent charring. Acid must be added with strong agitation at point of contact. |
| **10.4** | Conditions to be avoided: | Avoid heat, open flames, and storage of product in unventilated storage tanks or containers. |
| **10.5** | Incompatible materials: | None known |
| **10.6** | Hazardous decomposition products: | Carbon monoxide, alcohol or fatty acid vapors. |

| **11. Toxicological information** | | |
|---|---|---|
| **11.1** | Information on toxicological effects: | |
| | Acute oral toxicity: | No data |
| | Acute skin toxicity: | No data |
| | Skin irritation: | May cause skin irritation. |
| | Eye irritation: | May cause eye irritation. |
| | **Further toxicity data** | |
| | Skin sensitivity: | No data |
| | Carcinogenicity: | No data |
| | Mutagenicity: | No data |
| | Reproductive toxicity: | No data |
| | Sub-acute toxicity: | No data |

# Molasses

| | | |
|---|---|---|
| | Listed in the National Toxicology Program (NTP) Report on Carcinogens: | ☐ Yes ☒ No |
| | International Agency for Research on Cancer (IARC) Monographs Potential Carcinogen: | ☐ Yes ☒ No |

## 12. Ecological information

| | | |
|---|---|---|
| **12.1** | Ecotoxicity: | Results in high Biological Oxygen Demand (BOD) and potential oxygen depletion of aquatic systems. |
| **12.2** | Persistence and Degradability: | No data |
| **12.3** | Bio accumulative Potential: | No data |
| **12.4** | Mobility in Soil: | No data |
| **12.5** | Results of PBT and vPvB Assessment: | No data |
| **12.5** | Other Adverse Effects: | No data |

## 13. Disposal considerations

| | | |
|---|---|---|
| **13.1** | **Methods for waste treatment:** | |
| | Packaging waste: | Empty containers or liners may retain some product residues. |
| | Product waste: | Collect and reclaim or dispose of residues at an approved facility, as applicable. |

## 14. Information regarding transport

| | | |
|---|---|---|
| **14.1** | UN Number: | None |
| **14.2** | UN Proper Shipping Name: | None |
| **14.3** | Transport Hazard Class(es): | None |
| **14.4** | Packing Group: | None |
| **14.5** | Environmental Hazards: | None |
| **14.6** | Transport in Bulk: | None |
| **14.7** | Special Precautions: | None |

## 15. Information regarding regulations

| | |
|---|---|
| **15.1** | Safety, health and environmental regulations/legislation specific for the substance or mixture: |
| | N/A |
| **15.2** | Evaluation of the chemical safety: |
| | N/A |

## 16. Other information

The information in this document is obtained from supplier information and publicly available sources and is believed to be accurate and represents the best information currently available to Westway Feed Products LLC. All data and numbers represented are typical. These may vary dependent of origin, production process, crop cycle, supplier or producer.

The content and format of this SDS is in accordance with federal Occupational Health and Safety Administration (OSHA) standards. The information provided in this SDS is provided for health, safety and environmental assessment by a professional user. This information does not warrant suitability for the buyer's uses. Any recommendations given here should be considered as general only and may not apply in your specific situation. All final recommendations should be made by a qualified person familiar with your particular circumstances.

Westway Feed Product LLC makes no warranty of merchantability or any other warranty, express or implied, with respect to such information, and we assume no liability resulting from its use. Based on the information from this document, users should make their own risk assessments and investigations to determine the suitability of the information for their particular purposes. In no event shall Westway Feed Products LLC or any of its entities be liable for any claims, losses, or damages of any third party or for lost profits or any special, indirect, incidental, consequential or exemplary damages, howsoever arising, even if Westway Feed Products LLC has been advised of the possibility of such damages.

# SAFETY DATA SHEET
## ABC-Olé

## 1. PRODUCT AND COMPANY IDENTIFICATION

**PRODUCT NAME:** **ABC-Olé**
**GENERAL USE:** **Bioremediation of halogenated organics and metals**

**MANUFACTURER:**

**Redox Tech, LLC**
200 Quade Drive
Cary, NC 27513
919-678-0140

**EMERGENCY TELEPHONE:**

Within USA and Canada: 1-800-424-9300
+1 703-527-3887 (collect calls accepted)

## 2. HAZARDS IDENTIFICATION

EMERGENCY OVERVIEW: Product is generally recognized as safe. May cause irritation exposure to eyes. Long term contact to skin may cause some drying and minor irritation.

## 3. COMPOSITION INFORMATION ON INGREDIENTS

Proprietary mixture of fatty acids, glycerol, hydrolyzed vegetable oil, emulsifying agent and dipotassium phosphate.

## 4. FIRST AID MEASURES

**EYES:** Immediately flush with water for up to 15 minutes. If irritation persists, seek medical attention.

**SKIN:** Rinse with water. Irritation is unlikely, but if irritation occurs or persists, seek medical attention.

**INGESTION:** Generally safe to ingest but not recommended.

**INHALATION:** No first aid required.

## 5. FIRE FIGHTING MEASURES

**EXTINGUISHING MEDIA:** Deluge with water

**FIRE/EXPLOSION HAZARDS:** Product is combustible only at temperatures above 600C

**FIRE FIGHTING PROCEDURES:** Use flooding with plenty of water, carbon dioxide or other inert gasses. Wear full protective clothing and self-contained breathing apparatus. Deluging with water is the best method to control combustion of the product.

**FLAMMABILITY LIMITS:** non-combustible

**SENSITIVITY TO IMPACT:** non-sensitive

**SENSITIVITY TO STATIC DISCHARGE:** non-senstive

# 6. ACCIDENTAL RELEASE MEASURES

Confine and collect spill. Transfer to an approved DOT container and properly dispose. Do not dispose of or rinse material into sewer, stormwater or surface water. Discharge of product to surface water could result in depressed dissolved oxygen levels and subsequent biological impacts.

# 7. HANDLING AND STORAGE

**HANDLING:** Protective gloves and safety glasses are recommended.

**STORAGE:** Keep dry. Use first in, first out storage system. Keep container tightly closed when not in use. Avoid contamination of opened product. Avoid contact with reducing agents.

# 8. EXPOSURE CONTROLS – PERSONAL PROTECTION

**EXPOSURE LIMITS**

| Chemical Name | ACGIH | OSHA | Supplier |
|---|---|---|---|
| **ABC** | **NA** | **NA** | **NA** |

**ENGINEERING CONTROLS:** None are required

**PERSONAL PROTECTIVE EQUIPMENT**

**EYES and FACE:** Safety glasses recommended
**RESPIRATOR:** none necessary
**PROTECTIVE CLOTHING:** None necessary
**GLOVES:** rubber, latex or neoprene recommended but not required

# 9. PHYSICAL AND CHEMICAL PROPERTIES

| | |
|---|---|
| Odor: | none to mild pleasant organic odor |
| Appearance: | milky |
| Auto-ignition Temperature | Non-combustible |
| Boiling Point | >600 C |

| | |
|---|---|
| Melting Point | NA |
| Density | 0.90 gram/cc |
| Solubility | infinite (miscible) |
| pH | 6-8 |

# 10. STABILITY AND REACTIVITY

**CONDITIONS TO AVOID:** Do not contact with strong oxidizers
**STABILITY:** product is stable
**POLYMERIZATION:** will not occur
**INCOMPATIBLE MATERIALS:** strong oxidizers
**HAZARDOUS DECOMPOSITION PRODUCTS:**

# 11. TOXICOLOGICAL INFORMATION

**Acute Toxicity**
A: General Product Information
Acute exposure may cause mild skin and eye irritation.
B: Component Analysis - LD50/LC50

No information available.

B: Component Analysis - TDLo/LDLo
TDLo (Oral-Man) none

**Carcinogenicity**
A: General Product Information
No information available.
B: Component Carcinogenicity
Product is not listed by ACGIH, IARC, OSHA, NIOSH, or NTP.

**Epidemiology**
No information available.

**Neurotoxicity**
No information available.

# 12. ECOLOGICAL INFORMATION

**Ecotoxicity**
Discharge to water may cause depressed dissolved oxygen and subsequent ecological stresses
**Environmental Fate**
No potential for food chain concentration

# 13. DISPOSAL CONSIDERATIONS

**DISPOSAL METHOD:** Material is not considered hazardous, but consult with local, state and federal agencies prior to disposal to ensure all applicable laws are met.

# 14. TRANSPORT INFORMATION

NOTE: The shipping classification information in this section (Section 14) is meant as a guide to the overall classification of the product. However, transportation classifications may be subject to change with changes in package size. Consult shipper requirements under I.M.O., I.C.A.O. (I.A.T.A.) and 49 CFR to assure regulatory compliance.

**US DOT Information**
Shipping Name: Not Regulated
Hazard Class: Not Classified
UN/NA #: Not Classified
Packing Group:None
Required Label(s):None

**50$^{th}$Edition International Air Transport Association (IATA):**
Not hazardous and not regulated

**INTERNATIONAL MARITIME DANGEROUS GOODS (IMDG)**

Material is not regulated under IMDG

# 15. REGULATORY INFORMATION

**UNITED STATES**

**SARA TITLE III**
SECTION 311 No Hazard for Immediate health Hazard
SECTION 312 No Threshold Quanitity
SECTION 313 Not listed

**CERCLA** NOT REGULATED UNDER CERCLA

**TSCA** NOT REGULATED UNDER TSCA

**CANADA (WHIMS):** NOT REGULATED

# 16. OTHER INFORMATION

HMIS:

| | |

# FerroBlack®-H

Safety Data Sheet

according to Federal Register / Vol. 77, No. 58 / Monday, March 26, 2012 / Rules and Regulations

Date of issue: 06/14/2016 Revision date: 06/14/2016 Supersedes: 06/25/2015

## SECTION 1: Identification

### 1.1. Identification

| | | |
|---|---|---|
| Product form | : | Mixture |
| Trade name | : | FerroBlack®-H |
| CAS No | : | 1317-37-9 |
| Formula | : | FeS |
| Synonyms | : | Ferrous sulfide / Iron sulfide / Iron sulphide / Iron(II) sulfide / Ferrous sulfide / Iron sulfide / Iron sulphide / Iron(II) sulfide |

### 1.2. Relevant identified uses of the substance or mixture and uses advised against

| | | |
|---|---|---|
| Use of the substance/mixture | : | Chemical used for the remediation of heavy metal(s) for liquid and solid wastes. |

### 1.3. Details of the supplier of the safety data sheet

Redox Technology Group, LLC
d/b/a Redox Solutions
1580 Research Way
Indianapolis, IN 46231

Company Contact: Jim Kissel
Telephone Number: (317) 660-6867 or (317) 412-3267

### 1.4. Emergency telephone number

CHEMTREC: (800) 424-9300

## SECTION 2: Hazard(s) identification

### 2.1. Classification of the substance or mixture

**GHS-US classification**

| | |
|---|---|
| Skin corrosion/irritation Category 2 | H315 |
| Serious eye damage/eye irritation Category 2A | H319 |

Full text of H statements : see section 16

### 2.2. Label elements

**GHS-US labeling**

Hazard pictograms (GHS-US) :

GHS07

Signal word (GHS-US) : Warning

Hazard statements (GHS-US) :
H315 - Causes skin irritation
H319 - Causes serious eye irritation

Precautionary statements (GHS-US) :
P264 - Wash hands thoroughly after handling
P280 - Wear eye protection, protective clothing, protective gloves
P302+P352 - If on skin: Wash with plenty of water
P305+P351+P338 - If in eyes: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing
P321 - Specific treatment (see Consult a doctor/medical service if you feel unwell on this label)
P332+P313 - If skin irritation occurs: Get medical advice/attention
P337+P313 - If eye irritation persists: Get medical advice/attention
P362+P364 - Take off contaminated clothing and wash it before reuse

### 2.3. Other hazards

**HMIS Classification:**
Health hazard: 0
Flammability: 0
Physical hazards: 0

**NFPA Rating:**
Health hazard: 1
Fire: 0
Reactivity Hazard: 0

**Inhalation** May be harmful if inhaled. May cause respiratory tract irritation.
**Skin** May be harmful if absorbed through skin. May cause skin irritation.
**Eyes** May cause eye irritation.
**Ingestion** May be harmful if swallowed.
**Other Hazards not contributing to the classification:** Generates toxic gas in contact with acid.

### 2.4. Unknown acute toxicity (GHS US)

Not applicable

## SECTION 3: Composition/Information on ingredients

### 3.1. Substance

Not applicable

### 3.2. Mixture

| Name | Product Identifier | % | GHS-US classification |
|---|---|---|---|
| Iron sulfide (FeS) | (CAS No) 1317-37-9 | 7 - 11 | Not classified |
| Sodium Sulfide | (CAS No) 1313-82-2 | 0.1 - 1 | Acute Tox. 3 (Oral), H301 |

Full text of hazard classes and H-statements : see section 16

## SECTION 4: First aid measures

### 4.1. Description of first aid measures

First-aid measures general : Never give anything by mouth to an unconscious person. If you feel unwell, seek medical advice (show the label where possible).

First-aid measures after inhalation : Remove person to fresh air and keep comfortable for breathing. Remove victim to fresh air and keep at rest in a position comfortable for breathing. Immediately call a poison center or doctor/physician.

First-aid measures after skin contact : Remove/Take off immediately all contaminated clothing. Rinse skin with water/shower. If skin irritation occurs: Get medical advice/attention.

First-aid measures after eye contact : Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing. Immediately call a doctor/physician. If eye irritation persists: Get medical advice/attention.

First-aid measures after ingestion : Rinse mouth. Do NOT induce vomiting. Immediately call a poison center or doctor/physician. Call a poison center/doctor/physician if you feel unwell.

### 4.2. Most important symptoms and effects, both acute and delayed

Symptoms/injuries : Causes skin and eye irritation.

Symptoms/injuries after skin contact : Irritation.

Symptoms/injuries after eye contact : Causes serious eye damage. Eye irritation.

### 4.3. Indication of any immediate medical attention and special treatment needed

Treat symptomatically.

## SECTION 5: Firefighting measures

### 5.1. Extinguishing media

Suitable extinguishing media : Foam. Dry powder. Carbon dioxide. Water spray. Sand.

Unsuitable extinguishing media : Do not use a heavy water stream.

### 5.2. Special hazards arising from the substance or mixture

Reactivity : Corrosive vapors.

### 5.3. Advice for firefighters

Firefighting instructions : Use water spray or fog for cooling exposed containers. Exercise caution when fighting any chemical fire. Prevent fire-fighting water from entering environment.

Protection during firefighting : Do not enter fire area without proper protective equipment, including respiratory protection. Do not attempt to take action without suitable protective equipment. Self-contained breathing apparatus. Complete protective clothing.

## SECTION 6: Accidental release measures

### 6.1. Personal precautions, protective equipment and emergency procedures

#### 6.1.1. For non-emergency personnel

Emergency procedures : Ventilate spillage area. Evacuate unnecessary personnel. Avoid contact with skin and eyes.

#### 6.1.2. For emergency responders

Protective equipment : Do not attempt to take action without suitable protective equipment. Equip cleanup crew with proper protection. For further information refer to section 8: "Exposure controls/personal protection".

Emergency procedures : Ventilate area.

### 6.2. Environmental precautions

Avoid release to the environment. Prevent entry to sewers and public waters. Notify authorities if liquid enters sewers or public waters.

### 6.3. Methods and material for containment and cleaning up

Methods for cleaning up : Take up liquid spill into absorbent material. Soak up spills with inert solids, such as clay or diatomaceous earth as soon as possible. Collect spillage. Store away from other materials.

Other information : Dispose of materials or solid residues at an authorized site.

### 6.4. Reference to other sections

See Heading 8. Exposure controls and personal protection. For further information refer to section 13.

## SECTION 7: Handling and storage

### 7.1. Precautions for safe handling

Precautions for safe handling : Ensure good ventilation of the work station. Wash hands and other exposed areas with mild soap and water before eating, drinking or smoking and when leaving work. Provide good ventilation in process area to prevent formation of vapor. Do not breathe dust, fume, gas, mist, spray, vapors. Avoid contact during pregnancy/while nursing. Avoid contact with skin and eyes. Wear personal protective equipment.

Hygiene measures : Wash hands thoroughly after handling. Wash contaminated clothing before reuse. Do not eat, drink or smoke when using this product. Always wash hands after handling the product.

### 7.2. Conditions for safe storage, including any incompatibilities

Technical measures : Comply with applicable regulations.

Storage conditions : Keep only in the original container in a cool, well ventilated place away from : Ignition sources, Incompatible materials. Keep container closed when not in use. Store in a well-ventilated place. Keep cool.

Incompatible products : Strong bases. Strong acids.

Incompatible materials : Sources of ignition. Direct sunlight.

## SECTION 8: Exposure controls/personal protection

### 8.1. Control parameters

**Iron sulfide (FeS) (1317-37-9)**

Not applicable

**Sodium sulfide (1313-82-2)**

Not applicable

### 8.2. Exposure controls

Appropriate engineering controls : Ensure good ventilation of the work station.

Personal protective equipment : Avoid all unnecessary exposure.

| | | |
|---|---|---|
| Hand protection | : | Wear protective gloves. |
| Eye protection | : | Chemical goggles or face shield. Safety glasses. |
| Skin and body protection | : | Wear suitable protective clothing. |
| Respiratory protection | : | Wear appropriate mask. |
| Environmental exposure controls | : | Avoid release to the environment. |
| Other information | : | Do not eat, drink or smoke during use. |

## SECTION 9: Physical and chemical properties

### 9.1. Information on basic physical and chemical properties

| | | |
|---|---|---|
| Physical state | : | Liquid |
| Appearance | : | Black liquid with visible suspended solids. |
| Color | : | Black |
| Odor | : | Mild |
| Odor threshold | : | No data available |
| pH | : | 11.0 - 12.5 |
| Melting point | : | Not applicable |
| Freezing point | : | No data available |
| Boiling point | : | No data available |
| Flash point | : | No data available |
| Relative evaporation rate (butyl acetate=1) | : | No data available |
| Flammability (solid, gas) | : | Non flammable. |
| Vapor pressure | : | No data available |
| Relative vapor density at 20 °C | : | No data available |
| Relative density | : | 1.15 - 1.22 |
| Solubility | : | Mininally soluble in water. |
| Log Pow | : | No data available |
| Auto-ignition temperature | : | No data available |
| Decomposition temperature | : | No data available |
| Viscosity, kinematic | : | No data available |
| Viscosity, dynamic | : | No data available |
| Explosion limits | : | No data available |
| Explosive properties | : | No data available |
| Oxidizing properties | : | No data available |

### 9.2. Other information

No additional information available

## SECTION 10: Stability and reactivity

### 10.1. Reactivity

Acidic vapors.

### 10.2. Chemical stability

Not established.

### 10.3. Possibility of hazardous reactions

Contact with acids liberates toxic gas.

### 10.4. Conditions to avoid

Direct sunlight. Extremely high or low temperatures.

### 10.5. Incompatible materials

Acids will cause the release of highly toxic Hydrogen Sulfide. Reacts violently with diazonium salts. Ferrous sulfide(s) solution is not compatible with copper, zinc, aluminum or their **alloys** (i.e. bronze, brass, galvanized metals, etc.). Corrosive to steel above 150º F (65.5º C). These materials of construction should not be used in handling systems or storage containers for this product.

### 10.6. Hazardous decomposition products

Hazardous decomposition products formed under fire may include sulfur oxides, iron oxides.

## SECTION 11: Toxicological information

### 11.1. Information on toxicological effects

Acute toxicity : Not classified

| Sodium Sulfide (113-82-2) | |
|---|---|
| LD50 oral rat | 208 mg/kg |
| ATE US (oral) | 208.000 mg/kg body weight |
| LD50 dermal rabbit | < 340 mg/kg |
| ATE US (dermal) | 300.000 mg/kg body weight |

Skin corrosion/irritation : Causes skin irritation.
pH: 11.0 - 12.5

Serious eye damage/irritation : Causes eye irritation.
pH: 11.0 - 12.5

Respiratory or skin sensitization : Not classified

Germ cell mutagenicity : Not classified

Carcinogenicity : Not classified

Reproductive toxicity : Not classified

Specific target organ toxicity (single exposure) : Not classified

Specific target organ toxicity (repeated exposure) : Not classified

Aspiration hazard : Not classified

Potential Adverse human health effects and symptoms : Based on available data, the classification criteria are not met.

Symptoms/injuries after skin contact : Irritation.

Symptoms/injuries after eye contact : Causes eye irritation.

## SECTION 12: Ecological information

### 12.1. Toxicity

Ecology - general : The product is not considered harmful to aquatic organisms or to cause long-term adverse effects in the environment.

| FeS (1317-37-9) | |
|---|---|
| LC50 fish 1 | > 10000 mg/l Mosquito fish |

| Sodium Sulfide (1313-82-2) | |
|---|---|
| LC50 fish 1 | 7.7 - 29.1 mg/l (Exposure time: 96 h - Species: Poecilia reticulata) |
| EC50 Daphnia 1 | 2.1 mg/l (Exposure time: 48 h - Species: Daphnia magna) |

### 12.2. Persistence and degradability

| Redox-Hg (1317-37-9) | |
|---|---|
| Persistence and degradability | Not established. |

### 12.3. Bioaccumulative potential

| FeS (1317-37-9) | |
|---|---|
| Bioaccumulative potential | Not established. |

| Sodium Sulfide (16721-80-5) | |
|---|---|
| Log Pow | -3.5 (at 25 °C) |

### 12.4. Mobility in soil

No additional information available

### 12.5. Other adverse effects

Effect on the global warming : No known effects from this product.
GWPmix comment : No known effects from this product.

Other information : Avoid release to the environment.

## SECTION 13: Disposal considerations

### 13.1. Waste treatment methods

Waste treatment methods : Dispose of contents/container in accordance with licensed collector's sorting instructions.
Waste disposal recommendations : Dispose of contents/container to hazardous or special waste collection point, in accordance with local, regional, national and/or international regulation.
Ecology - waste materials : Avoid release to the environment.

## SECTION 14: Transport information

**Department of Transportation (DOT)**

In accordance with DOT

Not Regulated

**Transport by sea**

Not Regulated

**Air transport**

Not Regulated

## SECTION 15: Regulatory information

### 15.1. US Federal regulations

| **Iron sulfide (FeS) (1317-37-9)** |
|---|
| Listed on the United States TSCA (Toxic Substances Control Act) inventory |

| **Sodium Sulfide (1313-82-2)** |
|---|
| Listed on the United States TSCA (Toxic Substances Control Act) inventory |

### 15.2. International regulations

**CANADA**

| **Iron sulfide (FeS) (1317-37-9)** | |
|---|---|
| Listed on the Canadian DSL (Domestic Substances List) | |
| WHMIS Classification | Uncontrolled product according to WHMIS classification criteria |

| **Sodium Sulfide (1313-82-2)** |
|---|
| Listed on the Canadian DSL (Domestic Substances List) |

**EU-Regulations**

| **Iron sulfide (FeS) (1317-37-9)** |
|---|
| Listed on the EEC inventory EINECS (European Inventory of Existing Commercial Chemical Substances) |

| **Sodium Sulfide (1313-82-2)** |
|---|
| Listed on the EEC inventory EINECS (European Inventory of Existing Commercial Chemical Substances) |

**National regulations**

| **Iron sulfide (FeS) (1317-37-9)** |
|---|
| Listed on the AICS (Australian Inventory of Chemical Substances)<br>Listed on IECSC (Inventory of Existing Chemical Substances Produced or Imported in China)<br>Listed on the Japanese ENCS (Existing & New Chemical Substances) inventory<br>Listed on the Korean ECL (Existing Chemicals List)<br>Listed on NZIoC (New Zealand Inventory of Chemicals)<br>Listed on PICCS (Philippines Inventory of Chemicals and Chemical Substances) |

| **Sodium Sulfide (1313-82-2)** |
|---|
| Listed on the AICS (Australian Inventory of Chemical Substances)<br>Listed on IECSC (Inventory of Existing Chemical Substances Produced or Imported in China)<br>Listed on the Japanese ENCS (Existing & New Chemical Substances) inventory<br>Listed on the Korean ECL (Existing Chemicals List)<br>Listed on NZIoC (New Zealand Inventory of Chemicals)<br>Listed on PICCS (Philippines Inventory of Chemicals and Chemical Substances)<br>Listed on INSQ (Mexican National Inventory of Chemical Substances)<br>Listed on CICR (Turkish Inventory and Control of Chemicals) |

### 15.3. US State regulations

| **Sodium Sulfide (1313-82-2)** |
|---|
| U.S. - Massachusetts - Right To Know List<br>U.S. - New Jersey - Right to Know Hazardous Substance List |

## SECTION 16: Other information

Revision date : 06/14/2016

Other information : None.

Full text of H-phrases:

| | |
|---|---|
| H301 | Toxic if swallowed |
| H315 | Causes skin irritation |
| H319 | Causes serious eye irritation |
| H400 | Very toxic to aquatic life |

SDS US (GHS HazCom 2012)

*This information is based on our current knowledge and is intended to describe the product for the purposes of health, safety and environmental requirements only. It should not therefore be construed as guaranteeing any specific property of the product*

# REMOTOX®
## SAFETY DATA SHEET

Issue Date: 11/01/2012 | Revision Date: 04/01/2019

## SECTION 1: PRODUCT AND COMPANY IDENTIFICATION

**1.1 Product identifier**

| | |
|---|---|
| Product Name | REMOTOX® |
| Chemical Name | Calcium Polysulfide Solution |
| Chemical Family | Inorganic Salt |
| CAS-No. | 1344-81-6 |

**1.2 Recommended use of the substance or mixture**

| | |
|---|---|
| Identified Uses | Industrial use. Heavy metal fixation agent. |

**1.3 Details of the supplier of the safety data sheet**

| | |
|---|---|
| Company | Graus Chemicals, LLC<br>P.O. Box 768<br>Carefree, AZ 85377<br>1-623-328-5175<br>info@grauschemicals.com |

**1.4 Emergency phone number** 1-888-255-3924 | CHEMTEL

## SECTION 2: HAZARD(S) IDENTIFICATION

**2.1 Classification of the substance or mixture**

| | |
|---|---|
| Acute toxicity – oral | Category 4 |
| Acute toxicity – dermal | Category 4 |
| Acute toxicity – inhalation | Category 4 |
| Skin corrosion/irritation | Category 2 |
| Eye damage/irritation | Category 1 |

**2.2 GHS-US labeling**

Signal word: Danger!

Hazard statement(s):

| | |
|---|---|
| H302 | Harmful if swallowed. |
| H315 | Causes skin irritation. |
| H318 | Causes serious eye damage. |
| H332 | Harmful if inhaled. |

Symbol(s):

Precautionary statement(s):

| | |
|---|---|
| P221 | Take any precaution to avoid mixing with ombustibles/acids/oxidizers. |
| P261 | Avoid breathing dust/fumes/gas/mist/vapors/spray. |
| P262 | Do not get in eyes, on skin, or on clothing. |
| P264 | Wash thoroughly after handling. |
| P233 | Keep containers tightly closed. |
| P271 | Use only outdoors or in a well-ventilated area. |
| P273 | Avoid release to the environment – if this is not the intended use. |
| P280 | Wear protective gloves/eye protection/face shield. |
| P501 | Dispose of contents/container in accordance with local/regional/ national/international regulations. |

Unclassified hazard(s): Acute aquatic toxicity

Unknown acute toxicity ingredient: None

## SECTION 3: COMPOSITION/INFORMATION ON INGREDIENTS

### 3.1 Substance/Mixture

| Chemical Name | Synonyms | Formula | CAS No. | EINECS No. | % by weight |
|---|---|---|---|---|---|
| Calcium Polysulfide | Lime Sulfur, Calcium Sulfide | $CaS_X/KS_X$ | 1344-81-6 | 215-709-2 | 26-34 |
| Water | Water | H2O | 7732-18-5 | 231-791-2 | Remaining |

## SECTION 4: FIRST AID MEASURES

### 4.1 Description of first aid measures

Eye contact — Rinse immediately (the exposed eyes) with lukewarm, gently flowing water for at least 15-20 minutes. Remove contact lenses, if present and easy to do. Continue rinsing. If eye irritation persists: Get immediate medical advice/attention.

Skin contact — Wash immediately with soap and plenty of water. Rinse for at least 15 minutes. Remove contaminated clothing and wash it before reuse. If skin irritation or rash occurs: Get medical advice/attention.

Ingestion — Drink immediately a small amount of water or milk. Then call a Poison Control Center or doctor/physician right away. Do not induce vomiting unless instructed by poison control or a medical professional.

Inhalation — Remove victim to fresh air and keep at rest in a position comfortable for breathing. If breathing is difficult, give oxygen. If not breathing, give artificial respiration. Get immediate medical advice/attention.

### 4.2 Most important symptoms and effects both acute and delayed

Acute — Eyes: Symptoms may include burns or irritation to the eyes.
Skin: Repeated or prolonged contact may cause dryness, cracking and dermatitis.
Inhalation: Symptoms may include irritation to the respiratory tract.
Ingestion: Symptoms may include burns or irritation of the gastrointestinal tract. Contact with stomach acid can liberate toxic hydrogen sulfide vapors.

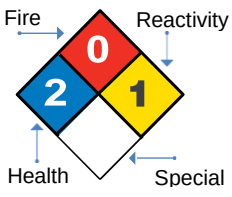
Delayed — No known chronic effects.

## SECTION 5: FIRE FIGHTING MEASURES

### 5.1 Flammable properties

National Fire Protection Association (NFPA) Ratings

| | |
|---|---|
| Health | 2 |
| Flammability | 0 |
| Reactivity | 1 |
| Special | - |



*HAZARD RATING:*
*4 SEVERE*
*3 SERIOUS*
*2 MODERATE*
*1 SLIGHT*
*0 MINIMAL*

### 5.2 Suitable extinguishing media

Use firefighting measures that suit the environment.

### 5.3 Unsuitable extinguishing media

No restrictions known.

### 5.4 Specific hazards arising from the substance or mixture

Closed/sealed containers may rupture violently when heated. In a fire, the following hazardous materials may be generated: hydrogen sulfide (H2S) gas.

**5.5 Protective equipment or precautions for firefighters**
Firefighters should wear self-contained breathing apparatus (SCBA) and full firefighting turnout gear. Keep containers and storage vessels in the fire area cooled with water spray.

## SECTION 6: ACCIDENTAL RELEASE MEASURES

**6.1 Personal precautions**
Wear protective equipment specified in Section 8. Isolate the release area and deny entry to unnecessary personnel.

**6.2 Environmental precautions**
Avoid release to the environment – if this is not the intended use. Dike spills and stop leakage where practical.

**6.3 Methods and materials for containment and cleaning up**

| | |
|---|---|
| Small releases | Use absorbent material to collect and contain for salvage or disposal. Clean surface thoroughly to remove residual spill. |
| Large releases | Shut off release if safe to do so. Dike spill area with earth, sand or other inert absorbents to prevent runoff into surface waterways or drains. Recover as much of the released product as possible, using portable pump and hoses, and place into container(s) for later disposal. Following product recovery, flush area with water. |

## SECTION 7: HANDLING AND STORAGE

**7.1 Precautions for safe handling**
Wear suitable protective clothing, gloves and eye/face protection. Use only in a well ventilated area. Avoid contact with skin and eyes. Avoid prolonged or repeated breathing of vapors. Wash skin thoroughly after handling.

**7.2 Conditions for safe storage, including any incompatibilities**
Store in well ventilated area and away from combustibles, acids and oxidizing agents. Keep away from heat. Keep containers tightly closed and store out of direct sunlight at a moderate temperature.

## SECTION 8: EXPOSURE CONTROL/PERSONAL PROTECTION

**8.1 Occupational exposure limits**
No exposure limits noted.

**8.2 Engineering controls**
Good ventilation should be used. Ventilation rates should be matched to site conditions. If applicable, use process enclosures, local exhaust ventilation, or other engineering controls to maintain airborne levels below reccommended exposure limits. If exposure limits have not been established, maintain airborne levels to an acceptable level. Provide eyewash station where material is frequently handled.

**8.3 Personal protection measures**

Eye Protection — Wear chemical goggles/full face shield. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN 166 EU).

Skin Protection — Wear neoprene rubber gloves and chemical protection suit to prevent repeated or prolonged contact with material. Use protective clothing tested and approved under appropriate government standards such as NIOSH (US) or Directive 89/686/EEC (EU).

| | | |
|---|---|---|
|  | Respiratory Protection | Have self-contained breathing apparatus (SCBA) positive pressure, available in case of accidental release, equipment failure or other unforeseen incidents. Use respirators and components tested and approved under appropriate government standards such as NIOSH (US) or EN 166 EU |
|  | General Hygiene Considerations | Wash thoroughly after handling and before eating, drinking or smoking. Routinely wash work clothing and protective equipment to remove contaminants. |

## SECTION 9: PHYSICAL AND CHEMICAL PROPERTIES

### 9.1 Information on basic physical and chemical properties

| | |
|---|---|
| Appearance | Deep red-yellow liquid |
| Upper/lower flammability limits | Not applicable |
| Odor | Slight rotten egg odor |
| Vapor pressure | Not determined |
| Odor threshold | 4.7 ppb (hydrogen sulfide) |
| Vapor density | Not determined |
| pH | 10.5-11.5 |
| Relative density | 1.27 g/cc or 10.6 lbs/gal |
| Melting point | Not applicable |
| Freezing point | 18-25 °F (-7.7 to -3.9 °C) |
| Solubility | Completely soluble in water |
| Initial Boiling point/range | Not determined |
| Flash point | Not applicable |
| Evaporation rate | Not determined |
| Flammability (solid, gas) | Not applicable |
| Partition coefficient | No data available |
| Auto ignition temperature | Not applicable |
| Decomposition temperature | Not determined |
| Viscosity | 2.95 cSt @ 20 °C, 2.5 cSt @ 30 °C |

## SECTION 10: STABILITY AND REACTIVITY

### 10.1 Reactivity
Strong oxidizers and acids.

### 10.2 Chemical stability
Stable under moderate temperature and pressure.

### 10.3 Possibility of hazardous interactions
Acids, acidic materials, and strong oxidizers cause rapid decomposition, resulting in the formation of $H_2S$ gas.

### 10.4 Conditions to avoid
Fire, excessive heat and freezing conditions.

### 10.5 Incompatible materials
Chemical substances: Acids, acidic materials and oxidizing agents. Materials of construction: Copper, carbon steel, aluminum or their alloys (i.e. brass, bronze, etc.).

### 10.6 Hazardous decomposition products
Hydrogen sulfide and oxides of sulfur.

## SECTION 11: TOXICOLOGICAL INFORMATION

| | | |
|---|---|---|
| Oral | Rat | $LD_{50}$: 820 mg/kg |
| Dermal | Rabbit | $LD_{50}$: >2,000 mg/kg |
| Inhalation | Rat | $LC_{50}$: 3.9 mg/l (4 hr exposure) male rat |
| | | $LC_{50}$: 3.1 mg/l (4 hr exposure) female rat |
| Eye | | Primary eye irritation. Possible risk of irreversible effects. |
| Carcinogenicity | | Not listed in NTP, IARC or by OSHA. |
| Teratology | | No data available. |
| Reproduction | | No data available. |
| Mutagenicity | | No data available. |

## SECTION 12: ECOLOGICAL INFORMATION

**12.1 Ecotoxicity**

| | |
|---|---|
| Green Algae | $EC_{50}$: 16.4 mg/l |
| Water Flea | $EC_{50}$: 13.7 mg/l |
| Bluegill | $LC_{50}$: 52.9 mg/l |
| Fathead Minnow | $LC_{50}$: 42.9 mg/l |
| Rainbow trout | $LC_{50}$: 8.8 mg/l |
| Honey Bee | $LD_{50}$: >25 µg ai/Bee |
| Avian | $LD_{50}$: 560 ai/kg |
| Bobwhite Quail | $LD_{50}$: 560 ai/kg body wt. |

**12.2 Persistence and degradability**
Calcium Polysulfide present in moist soils and/or moist foliage is expected to dissociate rapidly; therefore, run-off and erosion into surface waters, as present calcium polysulfide, should be negligible. (US EPA 2005, RED)

**12.3 Bioaccumulation potential**
Product is not bio-accumulative.

**12.4 Mobility in soil**
No data available.

**12.5 Other adverse effects**
Toxic to aquatic organisms.

## SECTION 13: DISPOSAL CONSIDERATION

**13.1 Waste treatment methods**
Do not contaminate ponds, waterways or ditches with chemical or used container. Dispose of contents/container in accordance with the local/regional/national/international regulations.

## SECTION 14: TRANSPORTATION INFORMATION

**14.1 Basic shipping information**

| | | |
|---|---|---|
| Proper shipping name | Calcium Polysulfide Solution | *(not regulated by US DOT)* |
| DOT Hazard Class | Not applicable | |
| UN Number | Not applicable | |
| Packing Group | Not applicable | |
| Placard(s) | Not applicable | |
| Labels | Not applicable | |
| Hazardous Substance | No | |
| Reportable quantity | No | |

| | | |
|---|---|---|
| **14.3** | **USCG Classification** | Not determined |
| **14.4** | **International Transportation** | |
| | IMO | UN3082, Environmentally Hazardous Substance, liquid, n.o.s., (Calcium Polysulfide) 9, PG III, MARINE POLLUTANT |
| | IATA | Not regulated |
| | TDG (Canada) | Not regulated |
| | ADR (Europe) | UN3082, Environmentally Hazardous Substance, liquid, n.o.s., (Calcium Polysulfide) 9, PG III, MARINE POLLUTANT |
| | ADG (Australia) | UN3082, Environmentally Hazardous Substance, liquid, n.o.s., (Calcium Polysulfide) 9, PG III, MARINE POLLUTANT |
| **14.5** | **Emergency Response Guide** | Not applicable |
| **14.6** | **ERAP (Canada)** | Not applicable |
| **14.7** | **Special Precautions** | Not applicable |

## SECTION 15: REGULATORY INFORMATION

| | | | |
|---|---|---|---|
| **15.1** | **US Federal Regulations** | | |
| | OSHA | Meets the definition of a hazardous substance under the Federal OSHA Hazard Communication Standard (29 CFR 1910.1200). | |
| | TSCA | Included in the US EPA TSCA Inventory List. | |
| | CERCLA | Reportable quantity: No | |
| | SARA Title III | Extremely Hazardous Substance (EHS): No | |
| | | Section 312 (Tier II) Ratings: | Immediate (acute): Yes |
| | | | Fire: No |
| | | | Sudden release No |
| | | | Reactivity: No |
| | | | Delayed (chronic) No |
| | | Section 313 (Form R): | Not applicable |
| | RCRA | Not applicable | |
| | CAA (HAP): | Not applicable | |
| **15.2** | **State Regulations** | CA Prop 65: Not applicable | |
| **15.3** | **International Regulations** | | |
| | WHMIS (Canada) | Not determined | |
| | DSL/NDSL (Canada) | Listed in NDSL, Record No. 28636 | |

## SECTION 16: OTHER INFORMATION

**16.1 Use of Substance/Preparation**

This material is used for heavy metal removal in soil, groundwater and wastewater. Its use varies depending on the site and remediation technology employed. Therefore, exposure should be evaluated so that appropriate handling practices and training can be established to ensure safet workplace operations.

Some of the information presented are from sources other than direct test data on the product itself. The information in this Safety Data Sheet (SDS) was obtained from sources which we believe are reliable. However, the information is provided without any warranty, expressed or implied, regarding the correctness. The conditions or methods of handling, storage, use and disposal of the product are beyond our control and may be beyond our knowledge. For this and other reasons, we do not assume responsibility and expressly disclaim liability for loss, damage, or expense arising out of or in any way connected with the handling, use or disposal of the product. This SDS was prepared and is to be used only for this product. If the product is used as a component in another product, this SDS may not be applicable. Graus Chemicals reserves the right to revise this SDS periodically as new information becomes available.

| | PCE Monitoring Wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature<br>2. **Lab Analytical**: Chlorinated Ethenes only | Monthly (for injection areas in operation) |
| Post-Treatment Monitoring | Monitoring and Injection Wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature<br>2. **Lab Analytical**: Total and dissolved TAL metals, total and dissolved $Cr^{+6}$, TOC, sulfate/sulfide, and methane | 1st quarter following end of operation |
| | | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature<br>2. **Lab Analytical**: Total and dissolved TAL metals, TOC, sulfate | Quarterly following end of operation for up to 2 years |
| | PCE Monitoring Wells | 1. **Field Parameters**: DTW, pH, conductivity, DO, ORP, turbidity, and temperature | Quarterly, following end of operation for up to 2 years |
| | | 2. **Lab Analytical:** Chlorinated Ethenes only | |

**Notes:**

1. The monitoring location, parameters, and frequencies presented in this table serve as general guidance for IRM-related monitoring activities and may be adjusted based on Phase III IRM performance, injection areas in operation, and observed monitoring results.
2. Samples for analysis of dissolved-phase metals will be field-filtered prior to sample collection.

Cr = chromium
$Cr^{+6}$ = hexavalent chromium
DO = dissolved oxygen
DTW = depth to water
IRM = interim remedial measure
ORP = oxidation-reduction potential
PBR = Permit-By-Rule
PCE = tetrachloroethene
TAL = Target Analyte List
TOC = total organic carbon

## SECTION A. SITE NAME AND LOCATION

Site Name: Garfield Avenue Group Sites

AKAs: See Attachment 1

Street Address: See Attachment 1

Municipality: Jersey City (*Township, Borough or City*)

County: Hudson County Zip Code: 07305

Program Interest (PI) Number(s): See Attachment 1

Case Tracking Number(s) for this submission: See Attachment 1

Municipal block(s) and lot(s) where the **proposed discharge(s)** would occur:

Block # See Attachment Lot #(s) _____ Block # _____ Lot #(s) _____

Block # _____ Lot #(s) _____ Block # _____ Lot #(s) _____

## SECTION B. FEE AND DISCHARGE INFORMATION

DGW Proposal Review Fee ..... $350.00

**Discharge Type** *(check all that apply)*

☐ Discharge of Recovered Ground Water

Will the discharge be a result of dewatering only? ..... ☐ Yes ☐ No

☒ Discharge that is part of an *In situ* Remediation

☐ Discharges other than those above *(see instructions for more information)*

**Facility Type** *(check all that apply)*

☒ Underground Injection Control (UIC) facility (i.e., any type of injection)

☐ Non-UIC (e.g., surface application) *(see instructions for more information)*

**Attach a Discharge to Ground Water Proposal to this form** *(see instructions)*

## SECTION C. PUBLIC NOTICE PROVISIONS *(Does not apply to residential heating oil tank cases)*

Is the proposed discharge lasting greater than 180 days? ..... ☒ Yes ☐ No

If "Yes," attach a copy of the public notice written as you intend it to be published. *(see instructions)*

## SECTION D. SITE USE AND GROUND WATER CLASSIFICATION

**Current Site Use** *(check all that apply)*

☐ Industrial ☐ Agricultural
☐ Residential ☐ Park or recreational use
☒ Commercial ☒ Vacant
☐ School or child care ☐ Government
☒ Other Roadways

**Intended Future Site Use** *(check all that apply)*

☐ Industrial ☒ Park or recreational use
☒ Residential ☐ Vacant
☒ Commercial ☐ Government
☐ School or child care ☐ Future site use unknown

What is the ground water classification for this site as per N.J.A.C. 7:9C? *(check all that apply)*

☐ Class I-A ☒ Class II-A
☐ Class I-PL Pinelands Protection Area ☐ Class III-A
☐ Class I-PL Pinelands Preservation Area ☐ Class III-B

## SECTION E. RECEPTOR EVALUATION SUMMARY

### Non-UHOT Cases

1. Have any of the following been identified on the site or within 200 feet of the site boundary?

   Check all that apply.

   ☒ Residences
   ☐ Child care facilities
   ☐ Public and private schools (K-12)
   ☐ Surface water
   ☒ Other occupied buildings
   ☒ Public parks and playgrounds

2. Did the well search conducted as a part of the receptor evaluation show any well use (potable, industrial, or irrigation)? ☒ Yes ☐ No

   If "Yes," indicate the type of use and approximate distance (closest occurrence) from site: *(Check all that apply)*

   ☒ Potable Distance from site: 6500 feet
   ☒ Industrial Distance from site: 670 feet
   ☒ Irrigation Distance from site: 3700 feet

3. Have any of these receptors been impacted? ☐ Yes ☒ No
   If "Yes," Do you have an NJDEP assigned Case Manager? ☐ Yes ☐ No

   If "Yes," please list the Case Manager: _____

### UHOT Cases

1. Is ground water contamination above the Ground Water Remediation Standards? ☐ Yes ☐ No
   If "Yes," answer questions 2 and 3.
2. Has a potable well been identified within 100 feet of the contamination? ☐ Yes ☐ No
3. Have any potable wells been impacted? ☐ Yes ☐ No
   If "Yes," has the NJDEP been notified? ☐ Yes ☐ No

## SECTION F. PERSON RESPONSIBLE FOR CONDUCTING THE REMEDIATION INFORMATION AND CERTIFICATION

Full Legal Name of the Person Responsible for Conducting the Remediation: PPG

Representative First Name: Mark Representative Last Name: Terril

Title: Corporate Director, Environmental Affairs

Telephone Number: (412) 434-2780 Ext.: _____ FAX: _____

Mailing Address: One PPG Place

City/Town: Pittsburgh State: PA Zip Code: 15222

Email Address: terril@ppg.com

This certification shall be signed by the person responsible for conducting the remediation who is submitting this notification in accordance with Administrative Requirements for the Remediation of Contaminated Sites rule at N.J.A.C. 7:26C-1.5(a).

*I certify under penalty of law that I have personally examined and am familiar with the information submitted herein, including all attached documents, and that based on my inquiry of those individuals immediately responsible for obtaining the information, to the best of my knowledge, I believe that the submitted information is true, accurate and complete. I am aware that there are significant civil penalties for knowingly submitting false, inaccurate or incomplete information and that I am committing a crime of the fourth degree if I make a written false statement which I do not believe to be true. I am also aware that if I knowingly direct or authorize the violation of any statute, I am personally liable for the penalties.*

Signature: Mark Terril Date: April 19, 2021

Name/Title: Mark Terril, Corporate Director, Environmental Affairs

☐ Check this box if the person above is also the property owner of the site or their representative. If this person is not the site property owner, please ensure the site property owner's name and address is included in the DGW Proposal, and also indicate that the property owner has been informed about the proposed discharge.

**SECTION G. LICENSED SITE REMEDIATION PROFESSIONAL INFORMATION AND STATEMENT**

LSRP ID Number: _____

First Name: _____ Last Name: _____

Phone Numbers: _____ Ext.: _____ Fax: _____

Mailing Address: _____

Municipality: _____ State: _____ Zip Code: _____

Email Address: _____

This statement shall be signed by the LSRP who is submitting this notification in accordance with N.J.S.A. 58:10C-14, and N.J.S.A. 58:10B-1.3b(1) and (2).

*(1) I certify, as a Licensed Site Remediation Professional authorized pursuant to N.J.S.A. 58:10C-1 et seq. to conduct business in New Jersey, that for the remediation described in this submission, and all attachments included in this submission, I personally: Managed, supervised, or performed the remediation conducted at this site that is described in this submission, and all attachments included in this submission; and/or periodically reviewed and evaluated the work performed by other persons that forms the basis for the information in this submission; and/or completed the work of another site remediation professional, licensed or not, after having: (1) reviewed all available documentation on which I relied; (2) conducted a site visit and observed the then-current conditions and verified the status of as much of the work as was reasonably observable; and (3)concluded, in the exercise of my independent professional judgment, that there was sufficient information upon which to complete any additional phase of remediation and prepare workplans and reports related thereto.*

*(2) I certify:*

- *That I have read this submission and all attachments to this submission;*
- *That in performing the professional services as the licensed site remediation professional for the entire site or each area of concern, I adhered to the professional conduct standards and requirements governing licensed site remediation professionals provided in N.J.S.A. 58:10C-16;*
- *That the remediation conducted at the entire site or each area of concern, that is described in this submission and all attachments to this submission, was conducted pursuant to and in compliance with the remediation requirements in N.J.S.A. 58:10C-14.c;*
- *That the remediation described in this submission, and all attachments to this submission, was conducted pursuant to and in compliance with the regulations of the Site Remediation Professional Licensing Board at N.J.A.C. 7:26I; and*
- *That the information contained in this submission and all attachments to this submission is true, accurate, and complete.*

*(3) I certify, when this submission includes a response action outcome, that the entire site or each area of concern has been remediated in compliance with all applicable statutes, rules, and regulations and is protective of public health and safety and the environment.*

*(4) I certify that no other person is authorized or able to use any password, encryption method, or electronic signature that the Board or the Department have provided to me.*

*(5) I certify that I understand and acknowledge that:*

- *If I knowingly make a false statement, representation, or certification in any document or information I submit to the Department I may be subject to civil and administrative enforcement pursuant to N.J.S.A. 58:10C-17.a.1(a)through (f) by the Board, including but not limited to license suspension, revocation, or denial of renewal; and*
- *If I purposely, knowingly, or recklessly make a false statement, representation, or certification in any application, form, record, document or other information submitted to the Department or required to be maintained pursuant to the Site Remediation Reform Act, I shall be guilty, upon conviction, of a crime of the third degree and shall, notwithstanding the provisions of subsection b. of N.J.S.2C:43-3, be subject to a fine of not less than $5,000 nor more than $75,000 per day of violation, or by imprisonment, or both.*

*(6) I certify that I have read this certification prior to signing, certifying, and making this submission.*

LSRP Signature: _____ Date: _____

LSRP Name: _____

Company Name: _____

**SECTION G. SUBSURFACE EVALUATOR UST REPORT CERTIFICATION FORM**

*I certify under penalty of law that the work was performed under my oversight and I have reviewed the report and all attached documents, and the submitted information is true, accurate and complete in accordance with the requirements of N.J.A.C. 7:14B and N.J.A.C. 7:26E. I am aware that there are significant civil and criminal penalties for submitting false, inaccurate or incomplete information including fines and/or imprisonment.*

Site Remediation Program
NJ Department of Environmental Protection
401-05H
PO Box 420
Trenton, NJ 08625-0420

## Draft Public Notice

Take notice that, as part of the remediation of the Garfield Avenue Group Sites (refer to Table 1) in Jersey City, Hudson County, a proposal has been submitted to the New Jersey Department of Environmental Protection (Department) to discharge to ground water in accordance with a permit issued pursuant to the provisions of the New Jersey Water Pollution Control Act, N.J.S.A. 58:10A-1 et seq., its implementing regulations the New Jersey Pollutant Discharge Elimination System, N.J.A.C. 7:14A; the Ground Water Quality Standards, N.J.A.C. 7:9C; and the Technical Requirements for Site Remediation, N.J.A.C. 7:26E. The Department's Site Remediation Program is reviewing the proposal to discharge to ground water for the purpose of remediating the contaminated sites with the program interest numbers, provided in Table 1 below.

Brief description of the proposed discharge: The Phase III Interim Remedial Measure (IRM) will be implemented at the Garfield Avenue Group Sites and select surrounding properties (herein collectively referred to as the “Project Area”), located in Jersey City, Hudson County, New Jersey. The Project Area is located on the Jersey City peninsula, approximately midway between the Passaic River and Hackensack River junction to the west (approximately 1.8 miles) and the upper bay/mouth of the Hudson River to the east (approximately 1.6 miles). The local overburden geology is generally consistent with the regional geologic mapping, and includes approximately 16 feet of poorly sorted fill materials over organic carbon-rich meadow mat. The meadow mat occurs over a large portion of the Project Area, and where present, marks the transition from the shallow fill aquifer to the intermediate and deep aquifers.

The proposed IRM will include discharge of biological and/or chemical reagents to facilitate in situ anaerobic bioprecipitation (ISAB) or in situ chemical reduction (ISCR) of targeted groundwater contaminants of concern. Within the overburden, ISAB will be achieved by injecting organic carbon substrates (i.e., molasses and/or emulsified vegetable oil [EVO]) into targeted vertical zones to stimulate a native microbial community for reducing hexavalent chromium ($Cr^{+6}$) to the less toxic, and less mobile trivalent chromium ($Cr^{+3}$) form, which will eventually be precipitated out of the aqueous phase and permanently fixed in the soil formation as insoluble precipitates. ISCR will be achieved by injecting calcium polysulfide (CPS) or by emplacing FerroBlack®-H into targeted vertical zones, to establish geochemically reducing conditions to achieve direct abiotic reduction of $Cr^{+6}$ to $Cr^{+3}$ and subsequent precipitation as $Cr^{+3}$-solids similar to the ISAB approach.

A copy of the discharge to ground water proposal is available from the person responsible for conducting the remediation (Mark Terril, One PPG Place, Pittsburgh, PA 15222), or as part of the administrative record which is on file at the offices of the Department, Site Remediation Program, located at 401 East State Street, Trenton, Mercer County, New Jersey. The file may be reviewed under the New Jersey Open Public Records Act ("OPRA"), N.J.S.A. 47:1A-1 et seq. Information regarding the OPRA procedures is available at www.state.nj.us/dep/opra/oprainfo.html. A copy of this public notice has been sent to the

Municipal Clerk and the designated Local Health Official for Jersey City and Hudson County, New Jersey.

Interested persons may submit written comments regarding the discharge to ground water proposal to the Department at the address listed below and to the owner or operator of the facility at [name and address of person/contact submitting discharge to ground water proposal]. All comments shall be submitted within 30 calendar days after the date of this public notice, or the end of any public hearing that the Department may schedule that occurs after that date. All persons who believe that the discharge to ground water proposal is inappropriate, must raise all reasonably ascertainable issues and submit in writing to the Department all reasonably available arguments and factual grounds supporting their position, including all supporting material, by the close of the public comment period. The Department will consider all public comments that relate to the discharge to ground water proposal, provided that the Department receives the comments by the close of the public comment period. After the close of the public comment period, the Department will render a decision regarding the proposed discharge to ground water.

The Department will respond to all significant and timely comments with its decision regarding the discharge to ground water proposal. Each person who has submitted written comments will receive notice of the Department's decision.

Any person may request in writing that the Department hold a non-adversarial public hearing on the discharge to ground water proposal. This request shall state the nature of the issues to be raised in the proposed hearing and shall be submitted within 30 calendar days of the date of this public notice to the address cited below. A public hearing will be conducted whenever the Department determines that there is a significant degree of public interest in the discharge to ground water decision. If a public hearing is held, the public comment period in this notice shall automatically be extended to the close of the public hearing.

Comments and written requests for a non-adversarial public hearing shall be sent to:

Re: Discharge to Ground Water Authorization (Phase III IRM)
Garfield Avenue Group Sites (Sites 114, 132, 133, 135, 137, and 143)
900 Garfield Avenue
Jersey City, Hudson County
Program Interest Numbers: G000008791 et al.
Subject Item ID: DGDW0000167710

Dear Mr. Terril,

This New Jersey Pollutant Discharge Elimination System/Discharge to Ground Water (NJPDES/DGW) authorization is hereby issued under the authority of the New Jersey Water Pollution Control Act, N.J.S.A. 58:10A-1 et seq. and the implementing regulations, N.J.A.C. 7:14A-1 et seq. N.J.A.C. 7:14A-7.5 authorizes the discharge described below which will allow the recovery and treatment of contaminated ground water, as well as implementation of in-situ remediation of contaminated ground water at the above referenced site.

Pursuant to N.J.A.C. 7:14A-22.4(b)5, a Treatment Works Approval is not required for discharges to ground water authorized pursuant to N.J.A.C. 7:14A-7.5 or 8.5 and a licensed operator is not required pursuant to N.J.A.C. 7:10A-1.10(c)1. The discharge approved through this authorization will be to a combination of permanent injection wells and to temporary injection points described below. The discharge shall be conducted as proposed in the 20 April 2021 Discharge to Groundwater Permit-by-Rule Authorization Request and DGW proposal, received on 20 April 2021 and clarified and revised by email on 4 June 2021 and 24 June 2021. These documents were submitted on your behalf by Joseph M. Luty, P.E. of AECOM.

A public notice describing this discharge was published in the Star Ledger on 4 May 2021 which initiated a 30 day public comment period. In addition, a copy of the public notice was sent to the clerk for the City of Jersey City and to the local health department. A response to comments document is attached.

Although the anticipated duration of injection activities is 15 months, PPG is requesting that the PBR be authorized for a full 5 years in case additional reagent injections are necessary to achieve the objectives. Pursuant to N.J.A.C. 7:14A-2.7 the maximum approved discharge duration is 5 years and it begins on the date the this discharge approval letter is issued. This authorized discharge shall not extend beyond 5 years from the date of this letter, regardless of the date when the discharge first occurs.

The Department shall be notified of the date when the discharge begins as instructed in section IV of this letter. Only the discharge described in Section I below is authorized. The discharge shall be conducted in conformance with the DGW proposal and shall comply with the requirements of Sections II, III, and IV, farther below.

## I. DISCHARGE DESCRIPTION

The authorized discharge includes organic carbon substrate (e.g., molasses and/or emulsified vegetable oil [EVO]) and/or two chemical reductants (FerroBlack®-H and calcium polysulfide [CPS]) which will be injected into areas described below. The clean water source for the mixture is the private water supply at the site.

The molasses and EVO substrates will provide a degradable source of organic carbon within the subsurface to support an in situ anaerobic bioprecipitation (ISAB) approach. FerroBlack®-H (a water based suspension of 7 to 11% by weight ferrous sulfide and 1 to 2% by weight sodium sulfide) and/or CPS solution (26 to 34% by weight calcium polysulfide) will also be used to support in situ chemical reduction (ISCR).

Site 114 is the former location of a chromite ore processing facility and a former manufactured gas plant, and encompasses 16.6 acres. The remaining five sites (Sites 132, 133, 135, 137, and 143) that comprise the Garfield Avenue Group are proximate to each other on abutting parcels. The total area encompassed by these five sites is 11.3 acres. The Phase III IRM area includes select portions of water-bearing zones within the following areas outside of Site 114: Carteret Avenue; select areas within HCC Sites 132, 137 and 143; Halladay Street North; intersection of Carteret Avenue and Pacific Avenue; in the vicinity of the 101 Pacific Avenue property; Forrest Street; and Site 199. The Phase III IRM also includes targeted treatment in strategic areas within the lower portion of the deep water-bearing zone on Site 114. Locations are shown on the attached figures. The target treatment areas for the Phase III IRM for the shallow, intermediate, and deep water-bearing zones will reach to depths of approximately 65 feet. An estimated minimum of 136 permanent injection wells will be installed, and may be supplemented with the use of direct push injections, as needed. Note that the number and location of proposed injection wells are approximate and subject to change based on Phase III IRM performance and observed monitoring results.

FerroBlack-H reactive zones are being considered for three target areas: (1) in the southwestern quadrant of Site 114 within the lower portion of the deep water-bearing zone l; (2) east of the intersection of Carteret and Pacific Avenues in the intermediate water-bearing zone; and (3) potentially on and/or immediately adjacent to Site 199 in the intermediate water-bearing zone. Boreholes will be spaced approximately 25 feet on-center along the transects. Boreholes will be pre-drilled using sonic techniques, and backfilled with bentonite. The injection probe will be

advanced using a direct-push technology through the bentonite to the target injection depths. It is estimated that approximately 300 gallons of FerroBlack-H suspension (i.e. 70 to 300 pounds FerroBlack-H in 300 gallons of water) will be injected every 3 feet vertically along the targeted depths.

Each of the three Area 1 FerroBlack-H reactive zones are anticipated to be approximately 250 feet in length perpendicular to the local groundwater flow direction, up to 15 feet in vertical thickness (depths ranging from 40 to 65 feet) and range up to 20 feet in horizontal thickness based on the total volume of FerroBlack-H to be emplaced in each reactive zone as depicted in the attached Figure 3-3. The focal area of the FerroBlack-H reactive zone in Area 2 east of Pacific Avenue is anticipated to be 180 feet in length in a line perpendicular to the local groundwater flow direction, approximately 40 feet in vertical thickness and range up to 20 feet in horizontal thickness. Additional contingency length beyond the target 180-feet is contemplated in the attached Figure 3-2. The Area 3 FerroBlack-H reactive zone along the boundary of Site 199 and Site 114 is anticipated to be approximately 135 feet in length, up to 30 feet in vertical thickness and range up to 15 feet in horizontal thickness as depicted in Figure 3-2. The lateral spacing of the soil borings will allow for overlapping radii of influence. The ultimate location and geometry of each reactive zone will be finalized during the design and ultimately during FerroBlack-H emplacement and will consider factors such as: utilities, access to non-PPG owned properties, structural stabilization of adjacent facilities, properties and structures, and proximity to the New Jersey (NJ) Transit Light Rail (on Site 199). The emplacement of the FerroBlack-H reactive zone near the boundary of Site 114 and Site 199 is conceptual and is being contemplated to address potential future mass flux in groundwater from green-gray mud remaining under the light rail on Site 199. A geotechnical evaluation is underway to determine the technical practicability of establishing a FerroBlack-H reactive zone near the boundary of Site 114 and Site 199 without disturbing the adjacent light rail and associated retaining wall structure. The reactive zone east of the intersection of Carteret and Pacific Avenues is designed to address the downgradient edge of Cr impacts for areas along Halladay Street that are not readily accessible for in situ injections. All final locations are subject to access.

In addition, a limited area within the shallow water-bearing zone on Site 199 is being targeted for treatment of tetrachloroethene (PCE). The attached Figure 3-1 shows the locations.

Although the anticipated duration of injection activities is 15 months, the PBR is authorized for a full 5 years in case additional reagent injections are necessary to achieve the objectives. The attached tables summarize the Sites and properties, and the anticipated volumes of reagents to be injected.

The injection of these products is designed to actively treat groundwater impacted with total chromium (Cr) and hexavalent chromium ($Cr^{+6}$) greater than 1000 µg/L in the shallow, intermediate, and deep water-bearing zones. Total chromium was reported as high as 600,000 µg/L. All four compounds have demonstrated their ability to reduce $Cr^{+6}$. In addition, a limited area within the shallow water-bearing zone on Site 199 is being targeted for treatment of tetrachloroethylene (PCE).

## II. SYSTEM OPERATION AND MONITORING

The area of discharge shall be monitored for evidence of malfunction. Said evidence shall include, but is not limited to: injection solution observation at land surface, wet areas, ponding, odors, and elevated PID readings in the nearby work area or building.

The discharge shall not cause any of the following negative impacts: adverse impact on the behavior of free product or the plume; adverse impacts to a water supply well or have a long term adverse impact on ground water quality; create an unpermitted discharge to any surface water of the State or violation of Surface Water Quality Standards; create a persistent standing, ponded or surface-flowing fluid condition; or cause adverse vapor intrusion to occur.

Pursuant N.J.A.C. 7:14A-6.2(a)5 and 11, if free product in ground water, vapors or odors in any building, or any malfunction resulting in a potential impact to a receptor are detected and are a result of the discharge authorized by this approval, the discharger will immediately: (1) cease the discharge or make necessary adjustments to the discharge rate or system operation; and (2) repair or mitigate any negative impacts.

After completion of the discharge, the property should be returned to its previous condition, or as agreed to with property owner if the permittee is not the property owner. All UIC-Class V injection wells shall be properly abandoned in accordance with N.J.A.C. 7:14A-8.16(d)1 as applicable. The permittee will comply with any applicable provisions of the Additional Conditions Applicable to Class I, II, III and V UIC Permits of the NJPDES regulations, N.J.A.C. 7:14A-8.9, et seq. when UIC-Class V injection well units (i.e., the injection points) are used.

## III. GROUND WATER MONITORING REQUIREMENTS

The Permittee shall perform the following ground water sampling as was specified in the DGW proposal (including all addendums and modifications) for the purpose of complying with this Discharge to Ground Water Permit-By-Rule authorization.

Baseline Sampling, before injection:

Baseline monitoring will be conducted prior to the start of operations. Groundwater will be analyzed for total and dissolved TAL metals, total and dissolved Cr, total organic carbon (TOC), sulfate/sulfide, and methane. Field parameters will include pH, conductivity, dissolved oxygen (DO), oxidation reduction potential (ORP), turbidity, and temperature. See attached Tables 4-1 and 4-2 for the list of wells.

Interim Sampling, during the injections:

Monthly groundwater samples will be collected within injection areas during operations. See attached Tables 4-1 and 4-2 for the list of wells. Analysis will be for total and dissolved Cr, TOC, and Sulfate. In the PCE treatment area, analysis will

include chlorinated ethenes. Field Parameters will include: pH, conductivity, DO, ORP, turbidity, and temperature.

Post Treatment Sampling, after completion of injections:

Quarterly sampling will be conducted for up to 2 years, See attached Tables 4-1 and 4-2 for the list of wells. Analysis will be for total and dissolved Cr, TOC, and Sulfate. In the PCE treatment area, analysis will include chlorinated ethenes. Field Parameters will include: pH, conductivity, DO, ORP, turbidity, and temperature.

Pursuant to the Tech Regs, the Permittee shall measure ground water elevations at all sampled wells upon each sampling event and shall construct ground water flow maps with the water elevation data to document the direction of ground water flow. Any product observed, including sheen, shall be documented. If measurable product is observed, injections shall be suspended until all of the recoverable product is removed from the treatment area.

All sampling shall be performed as proposed and consistent with the methods specified in the most current edition of the Department's Field Sampling Procedures Manual. All samples shall be analyzed by a New Jersey Certified Laboratory certified for the methods being used to analyze groundwater samples. Analytical method MDLs shall be less than or equal to the ground water quality standards (N.J.A.C. 7:9C-1.7). Parameters determined in the field (pH, specific conductance, dissolved oxygen, temperature) are to be measured by a certified contractor or laboratory.

Comparison to the vapor intrusion (VI) screening levels is necessary in order to monitor whether or not the discharge activities have the potential to cause VI issues within any nearby structures by means of adversely impacting the behavior of the ground-water contaminants (e.g., unexpected contaminant movement). If there are any exceedances of the VI screening levels caused by the authorized discharge, a VI evaluation shall be conducted of any potentially impacted structures.

Compliance with N.J.A.C. 7:26E-5.7(b) requires that the Permittee satisfy the post-injection ground water monitoring requirements that are set forth in this letter before applying for any Remedial Action Permit for Ground Water. If a Remedial Action Permit application is submitted before the required ground water sampling has been completed, the application will be denied.

Additionally, contingency compliance ground water sampling is required if ground water sampling results indicate that ground water quality criteria (GWQC) have been contravened because of the authorized discharge (e.g., the GWQC for sodium is exceeded as a result of sodium sulfide injection, or the GWQC for iron is exceeded as a result of FerroBlack-H), or that ground water quality has not returned to baseline conditions (when baseline concentrations are greater than GWQC) in the expected timeframe. Ground water sampling must continue until it can be demonstrated that the GWQC have been met or until the ground water quality has returned to baseline conditions. To demonstrate either of these conditions, a minimum of two consecutive ground water sampling events spaced far enough apart to account for seasonal fluctuations, must be conducted.

Furthermore, if the Permittee is planning to apply for a Ground Water Remedial Action Permit for Natural Attenuation in the future, and exceedances of the GWQC that are due to the discharge remain, those exceedances must be treated similarly to any other site related contaminants (i.e., a sufficient

number of samples are required and a decreasing concentration trend must be evident) consistent with the Department's Remedial Action Permits for Ground Water Guidance.

## IV. REPORTING REQUIREMENTS AND INFORMATION SUBMITTALS

Details of the well and system installation, system operation, and operation and treatment monitoring results associated with the Phase III IRM will be documented as part of quarterly technical status reports submitted to NJDEP. These quarterly status reports will include succinct, high-level summaries of activities performed, data collected and graphs depicting apparent trends, adaptive steps taken to modify or optimize Phase III treatment, and an overview of activities planned for the subsequent quarter. Pursuant to N.J.A.C. 7:26E-5.7(b), the person responsible for conducting the remediation shall present and discuss in the remedial action report all of the information identified or collected pursuant to N.J.A.C. 7:26E-5.1 through 5.6.

Succinct performance summary results will be submitted as part of quarterly status reports. All information, including a complete summary of the work performed under the PBR, a complete set of the data collected, a summary of data trends, an evaluation and interpretation of the data, and conclusions reached (as well as the QA/QC package specified at N.J.A.C. 7:26E-2.1(a)15) shall be submitted as part of the completion report within 6 months following cessation of active Phase II operation. All information shall be submitted to:

NEW JERSEY DEPARTMENT OF ENVIRONMENTAL PROTECTION
BUREAU OF CASE ASSIGNMENT & INITIAL NOTICE
MAILCODE 401-05H
P.O. BOX 420
TRENTON, NJ 08625-0420
ATTN: COPR

Consistent with N.J.A.C. 7:14A-2.11(a) and 6.2(a)14, within 90 days after initiation of the discharge, notify the Department of the "start date" of the discharge. To report this date, send an email to Wayne.Howitz@dep.nj.gov stating the start date of the discharge.

Consistent with N.J.A.C. 7:14A-2.11(a) and 6.2(a)14, any malfunctions or non-compliance should be reported by telephone within 24 hours to the Bureau of Ground Water Pollution Abatement at (609) 292-8427 and in writing within seven days. Written submissions must include the facility name and PI Number. Failure to report this information is a violation of N.J.A.C. 7:14A and the permit-by-rule.

Nothing in this correspondence affects your potential liability and obligations to the State Trustee, the Department or its Commissioner regarding natural resource injuries, restoration, or damages. Although this Phase III IRM is being approved as an interim remedial measure, PPG is planning to incorporate this effort into the overall final groundwater remediation strategy at the Garfield Avenue Group Sites. Approval of the IRM in this PBR does not constitute tacit approval of the final remedy proposed in the Groundwater Remedial Action Work Plan (AECOM, 31 March 2021) for the Garfield Avenue Group sites. Additional requirements in N.J.A.C. 7:26E-5.5 et seq. apply to any final remedial action workplans. Compliance with this PBR's post-treatment monitoring requirements

does not satisfy monitoring requirements for the final groundwater remedy. Consistent with N.J.A.C. 7:26E-5.2(a)3, the RAWP must demonstrate the effectiveness of the remedy in achieving the applicable remediation standards throughout the Garfield Avenue Group Sites.

If you have any questions or concerns associated with this Discharge Authorization, please contact Wayne Howitz of the Site Remediation Program at (609) 984-2905.

Sincerely,

Wayne C. Howitz, Assistant Director
Publicly Funded Remediation Element

Enclosure

| ISCR | Calcium Polysulfide (CPS) (2.75%) | See Note 2. | | | |
| | FerroBlack®-H[4] | Target Area 1 | Deep | 168,000 | 796,000 |
| | | | Contingency[3] | 168,000 | |
| | | Target Area 2 | Intermediate | 162,000 | |
| | | | Contingency[3] | 162,000 | |
| | | Target Area 3 | Intermediate | 68,000 | |
| | | | Contingency[3] | 68,000 | |

**Notes:**

1. Percentages noted in this column represent the design reagent-to-potable water concentrations proposed to be injected into the respective water bearing zones.

2. A CPS solution may be substituted for up to 50% of the anticipated injection volume of molasses (i.e., 8,120,000 gallons), if baseline or treatment monitoring data suggest the presence of areas of elevated hexavalent chromium concentrations (i.e., greater than 1,000,000 µg/L).

3. Contingency volumes account for an additional 100% of the estimated required injection volumes and may be implemented based on Treatment Monitoring.

4. FerroBlack®-H volumes were calculated using treatability study values derived from previous bench-scale and pilot-scale tests conducted in 2016. Actual volumes will be determined at the time of installation.

ISAB = *in situ* anaerobic bioprecipitation

ISCR = *in situ* chemical reduction

µg/L = micrograms per liter

AECOM

**Table 3**
**Approximate Mobile Pore Volumes for Treatment with Molasses/EVO/CPS**
**Permit-By-Rule Authorization Request - Phase III Groundwater Interim Remedial Measures**
**Garfield Avenue Group Sites**
**PPG, Jersey City, New Jersey**

| Water-Bearing Zone | Target Area 1 Mobile Pore Volume (Gallons) | Target Area 2 Mobile Pore Volume (Gallons) | Target Area 3 Mobile Pore Volume (Gallons) | Total Mobile Pore Volume (Gallons) |
|---|---|---|---|---|
| Shallow | 0 | 0 | 71,000 | **71,000** |
| Intermediate | 4,967,000 | 4,388,000 | 1,993,000 | **11,348,000** |
| Deep | 175,000 | 206,000 | 19,000 | **400,000** |
| **Combined** | **5,142,000** | **4,594,000** | **2,083,000** | **11,819,000** |

**Notes:**

1. Mobile pore volumes are estimated to be 15% of the total volume of soil and pore spaces. This assumption is consistant with the Phase I and Phase II Interim Remedial Measures.

EVO = Emulsified Vegitable Oil

CPS = Calcium Polysulfide

PPG will add four new monitoring well pairs to the Phase III IRM well network, as requested by the NJDEP in the 10 June 2021 email. A figure is attached. These wells will be named as follows:

- **Site 143:** 143-P3-MW002I-A and 143-P3-MW002I-B
- **Site 132:** 132-P3-MW001I-A and 132-P3-MW001I-B
- **Halsted:** HSTD-P3-MW002I-A/B and HSTD-P3-MW004I-A/B

## *Response to Comments Document*

Comment: Describe the technologies that are being considered for the emplacement of the in-situ reactive barriers (IRZs) depicted in the Groundwater RAWP. Describe how FerroBlack-H (FBH) will be incorporated into the IRZs.

Response: Boreholes will be pre-drilled with sonic drill, backfilled with bentonite, then the injection probe will be advanced to targeted depth. The issue is elaborated in Part I of the approval letter.

Comment: Can these technologies be used for treatment within the basal till zone? Is the basal till zone considered untreatable?

Response: PPG considers the basal till to be low permeability, and not practical for treatment.

Comment: How will the meadow mat, as an engineering control, be maintained and repaired if disturbed by the emplacement of the IRZs?

Response: The integrity of the meadow mat is preserved by backfilling the borings with hydrated bentonite in a tremie pipe fashion as the casing is withdrawn from each boring. This is described in Part I of the approval letter.

Comment: What are the general design parameters that will be used to determine the locations and dimensions for the IRZs?

Response: The dimensions of the target area for the FerroBlack-H reactive zones in the southwestern portion of Site 114 will vary per transect, but generally are as follows:

- Vertical thickness varies from < 5 feet to 15 feet
- Depths range from 40 to 65 feet below ground surface
- Lengths range from 250 to 350 feet.

The IRZs are described in Part I of the approval letter.

Comment: What additional data collection (e.g., bench tests, bucket tests, pilot test) will be undertaken to support the design of the IRZs?

Response: The estimated FerroBlack-H dosing (i.e., 70 to 300 pounds FerroBlack-H in 300 gallons of water per injection interval) was based on bench scale testing conducted by Redox Solutions.

Comment: What technologies will be used to map and verify the dimensions and hydraulic characteristics of the IRZs?

Response: Nested observation wells will be installed within reactive zone transects. Samples will be collected from the observation wells for geochemical and colorimetric evaluation (i.e., pH, oxidation-reduction potential [ORP], free sulfide, sample color). Monitoring requirement are described in Part III of the approval letter, and illustrated on attached figures.

Comment: What is the general approach to monitoring the IRZ system after emplacement to demonstrate long-term efficacy?

Response: Monitoring of the target treatment zone will proceed as per Appendix B of the PBR, which includes quarterly sampling of a set of existing and proposed monitoring wells for the first two years. Monitoring requirement are described in Part III of the approval letter, and illustrated on attached figures.

Post-PBR monitoring will be defined in the Active System Groundwater Remedial Action Permit (RAP) for the Garfield Avenue Group Sites.

Comment: What would be done to replace the FBH reductant once it is spent or if it does not achieve the design objectives, and how would replacement be conducted if redevelopment features are in the way?

Response: If supplemental injections are needed during initial emplacement mobilization, contingency volumes for FerroBlack-H were included in the PBR. If additional treatment is deemed necessary in the future, most of the target areas in the lower portion of the deep water-bearing zone will remain accessible following redevelopment as they are largely located within parking areas and outside the footprint of proposed buildings. This issue is relevant to the final groundwater remedial action.

Comment: Can case studies be provided for projects with similar size and depth parameters? Can case studies be provided for similar projects using FBH in deep vertical IRZs?

Response: Case studies were provided to New Jersey Department of Environmental Protection (NJDEP) via email on May 12, 2021. (There were no case studies using injection of FerroBlack-H.)

Comment: Why does the Site 143 area not have pairs of injection wells, and none in the deep zone?

Response: Using an adaptive management approach, adjustments will be made in field based on observations, and injection wells are expected to cover the entirety of the Phase III IRM area targeted for remediation. In several instances paired wells have been installed on Site 143 where only a single well was indicated in the PBR application.

Comment: Screen lengths were not specified in the proposal. The comment requested some clarification that the monitoring wells will have comparably long well screens (e.g., closer to 20 feet than 5 feet) consistent with the treatment zones.

Response: A table was provided, showing screen lengths, and a majority are 15 or 20 feet.

Comment: The Department requested four additional monitoring well pairs in the GW-IRM Phase 3 monitoring program.

Response: The four additional monitoring well pairs were added. The locations are provided on a figure, and are identified underneath Table 4-2, both attached to the PBR approval letter.

Comment: Requested the affidavit of publication for the Public Notice for the injections.

Response: The affidavit of publication was emailed on June 17, 2021.

|---|---|
| Subject | Geotechnical Evaluation of Proposed Groundwater Treatment within Site 199 and Forrest Street Properties – Phase III Groundwater Interim Remedial Measures<br>PPG Garfield Avenue Group, Hudson County Chromate Sites, Jersey City, New Jersey |
| Date | October 4, 2021 |

## 1. Introduction

On behalf of PPG, AECOM has prepared this technical memorandum to document the geotechnical evaluation of interim remedial measures (IRMs) proposed to address groundwater impacts at Site 199 and Forest Street Properties. Site 199 is located adjacent to the Hudson County Chromate Site 114, which is part of the Garfield Avenue (GA) Group Sites in Jersey City, Hudson County, New Jersey (NJ) (Project Area). Site 199 is part of the broader Phase III IRM area (see **Figure 1)** that includes select water-bearing zones outside of Site 114 and strategic areas of the lower portion of the deep water-bearing zone within Site 114.

Site 199 is adjacent to the NJ Transit Hudson-Bergen Light Rail (HBLR) tracks between Garfield Avenue and Halladay Street and the Forrest Street Properties which is referred to as “Target Area 1” in the April 20, 2021 Discharge to Groundwater Permit-By-Rule (PBR) Authorization Request (AECOM, 2021b). The objectives of the geotechnical evaluation (documented below) are: to determine if the IRM implementation can cause ground deformations (or pose other risks) that would disrupt HBLR operations; and to identify mitigation, limits, and controls that would facilitate safe implementation of the IRM at Site 199.

This technical memorandum provides the following information:

- Background information including a description of subsurface conditions and ground movements that occurred at the HBLR during Site 114 remediation (**Section 2**);
- Description of the Site 199 proposed IRMs and identification of potential risks to the HBLR posed by each activity (**Section 3**);
- Evaluation of the risks identified and the limits of controls required to mitigate those risks (**Section 4**);
- Geotechnical recommendations regarding IRM implementation (**Section 5**); and
- References for documents that are cited in the memorandum (**Section 6**).

## 2. Background

This section provides information on the geology and hydrogeology of the Project Area as well as a description of the previously observed settlement and vibration in the vicinity of the HBLR tracks during the installation of a shoring systems (sheet pile) and soil excavation conducted as part of the Site 114 remediation. This section also provides a discussion of the completed Phase I and ongoing Phase II groundwater IRMs.

The groundwater Cr plume within Site 199, which is the focus of the Phase III IRM, includes areas beneath the HBLR from Garfield Avenue to the Forest Street Properties. Sheet pile installed during the Site 114 remediation forms the boundary between Site 199 and Site 114. The HBLR tracks and catenary structures are elevated on an earth embankment supported by a concrete block retaining

wall. The embankment and retaining wall slope upward as the track approaches the Garfield Avenue bridge crossing.

## 2.1 Project Area Geology and Hydrogeology

The Project Area is located on miscellaneous fill material that was used to reclaim the salt marsh for the construction of this portion of Jersey City. Native materials beneath the fill include an organic meadow mat layer, unconsolidated deposits of glacial origin, and bedrock. The geology within the Project Area consists of:

- Fill (*the shallow zone*), comprised of:
    - Non-native fill materials in areas where soil remediation is not needed or has not yet been implemented. Native fill is present beneath Site 199 (north of the sheet pile).
    - Clean fill (unamended or amended with FerroBlack®-H reductant) where the previously existing non-native fill materials and subsurface structures were excavated to remove sources of chromium (Cr). Clean fill is present beneath Site 114 (south of the sheet pile).
- Underlying the fill, a discontinuous layer of estuarine organic-rich deposits (*meadow mat*);
- Underlying the meadow mat, or directly below the fill where the meadow mat is absent, native soils consisting of sands, silty sands, silts, and clays (*the intermediate zone*) generally separated from the underlying deep zone by a layer of interbedded lower permeability silts, clayey silts, silty sands, and clays (*the transition zone, part of the intermediate zone);*
- Underlying the intermediate zone, sands with lenses of silt, clay, and gravel underlain by the basal facies of the Rahway Till (*the deep zone, includes the basal till and overlying sands);* and
- Underlying the overburden, bedrock of the Lockatong and Stockton Formations with a diabase sill intruding into the Lockatong formation along the western edge of the Project Area (*the bedrock zone*).

Groundwater in the Project Area occurs within distinct hydrostratigraphic water-bearing zones (units), as follows:

- *Shallow Water-Bearing Zone*: includes groundwater present in the fill from the water table to the top of the meadow mat. Where the fill was excavated during soil remediation, the backfill is a more uniform dense-graded aggregate (DGA) material or DGA amended with FerroBlack®-H (A-DGA). In the northeastern corner of Site 114, beyond Forrest Street, a native sandy unit underlies the fill above the intermediate water-bearing zone deposits.
- *Intermediate Water-Bearing Zone:* includes groundwater present in the meadow mat, the underlying sand unit, and the transition zone. Where present, the meadow mat is the

transition zone between the shallow and intermediate water-bearing zones and generally limits vertical groundwater movement between these zones. Where meadow mat is absent, the shallow and intermediate water-bearing zones are in direct contact. Where present, the transition zone behaves like an aquitard due to its lower permeability. The intermediate water-bearing zone pinches out against the rising bedrock surface west of the Project Area (beyond Garfield Avenue).

- *Deep Water-Bearing Zone*: north of Carteret Avenue, the deep zone consists primarily of sand and gravel with lenses of clay or silt underlain by basal till. South of Carteret Avenue, the deep zone becomes more difficult to differentiate from the intermediate zone as both zones grade into thicker sequences of lower conductivity materials such as silts, clays, and fine sands with silt and clay. The deep water-bearing zone pinches out against the rising bedrock surface on the western margin of the Project Area near Garfield Avenue.

- *Bedrock Water-Bearing Zone:* consists primarily of the Lockatong Formation, with the Palisades Sill (diabase) along the western edge of the Project Area and a section of the Stockton Formation in the eastern portion of Site 114. Groundwater flow within the bedrock occurs only within interconnected bedrock fractures, bedding planes, cracks, and voids. Yields from bedrock wells in the Project Area are low (0.02 to 0.05 gallons per minute [gpm]). Groundwater flow in bedrock is a small fraction of the total groundwater flux through the Project Area.

The locations of two lithologic cross sections within Site 199 are shown on **Figure 2**. Cross sections depicting the geologic units and groundwater table are included on **Figure 3A** and **Figure 3B**. Results from geotechnical borings installed near or within Site 199 are included in **Attachment 1**.

## 2.2 Previously Observed Light Rail Ground Movements

Remediation activities, including the installation of sheet pile and excavation at Site 114, took place between 2013 and 2014 as a part of Phase 1C and Phase 2B-1. Site 114 is located at the intersection of Garfield Avenue and Carteret Avenue and the New Jersey Transit Right-of-Way (ROW) is located on the northwest boundary of Site 114. The HBLR runs within the ROW and the sheet pile installation and excavations occurred approximately 45 feet from the HBLR. This section describes movement and vibrations that occurred associated with the installation of the shoring systems (sheet piles) and the soil excavations.

### 2.2.1 Ground Movements During Shoring Installation

Sheet piles were installed parallel to the HBLR from April 25 to 29, 2013. During this time, a total of 39 sheets comprising approximately 162 linear feet to depths of 38.5 to 42.5 feet below ground surface were installed using a vibratory hammer. Two seismographs were used to continuously monitor vibration. These monitors were placed at the base of the retaining wall near RW-E and CP-H (see **Figure 4**). During this installation period, the vibration warning action limit of 0.5 inches/second and the stop work limit of 2.0 inches/second were exceeded. The maximum vibration observed was 2.5 inches per second.

Movement stop work levels (i.e., ±0.04 feet) at the retaining wall were exceeded on April 29, 2013 and work was subsequently stopped. The most significant movement along the retaining wall was observed within Row G. Movement at this location was measured as follows:

- Northing: -0.19 feet (movement towards the Site)
- Easting: -0.07 feet (movement towards Garfield Avenue)
- Elevation: -0.14 feet (movement downward)

Movement at the railroad ties was also observed as follows:

- Northing: -0.04 feet (movement towards the Site)
- Easting: 0.0 feet (i.e. no movement towards Garfield Avenue)
- Elevation: -0.01 feet (movement downward)

Settlement monitoring continued after the work stoppage at an increased frequency starting the week of April 29, 2013. The monitoring indicated slow, small-scale movement of the retaining wall, railroad ties, and catenary structures in a southerly direction (towards the Site) during the week of April 29 to May 5, 2013. Separation on the back side of the retaining wall between the wall and a concrete swale that runs behind the top of the wall, and between the concrete swale and the ground surface, was also visually observed during the week of April 29 to May 5, 2013. Sheet pile installation locations and indications of observed movement are shown on **Figure 4**.

As a result of the vibrations and settlement observed during the sheet pile installation, a revised design was developed. Shoring installation resumed on August 26, 2013 and was completed on October 4, 2013. During this time, sheet piles were installed using an ABI hydraulic press to reduce vibrations. No stop work exceedances of vibration or movement were observed during the use of the hydraulic press to install sheet piles.

The ground movement was likely due to vibration-induced consolidation of the loose fill, meadow mat soil, and loose soil lenses in the intermediate zone. Soil shifting during pre-drilling and excavation of obstructions along the shoring alignment may also have caused the movements.

### 2.3.2 Ground Movement During Excavations

On November 22, 2013, soil excavation between the permanent and temporary sheet pile began in Grid D. The excavation progressed west to east, with backfilling following excavation. Excavation between the sheet piles progressed slowly due to the need to iteratively install levels of bracing and the tight working environment between the sheet piles and bracing.

In mid-December 2013, AECOM observed an increase in the movement trend (as observed at settlement monitors) that appeared to be related to the ongoing excavation work. This trend slowed in late December, but movement (at a lower rate) was still observed (even in areas that had been backfilled) into January 2014. On January 17, 2014, a sudden increase in movement was observed over the course of the afternoon and evening. The excavation was backfilled and work was stopped.

Settlement monitoring was conducted on the retaining wall, rail lines, catenary structures, sheet pile, and nearby structures during the excavation work. Manual measurements were collected from March 26, 2013 to July 1, 2013 and real-time measurements began on July 1, 2013. From March 26, 2013 to January 21, 2014, the following minimum and maximum movements were observed:

**Settlement Monitoring Results – March 26, 2013 to January 21, 2014**

| Prism Location | Southing (inches) | | Elevation (inches) | |
|---|---|---|---|---|
| | Minimum | Maximum | Minimum | Maximum |
| Sheet Pile | 0.58 (SP-F) | 1.39 (SP-H) | -0.013 (SP-H) | -0.99 (SP-I) |
| Retaining Wall | 1.2 (RW-D) | 4.94 (RW-G) | -0.12 (RW-D) | -3.02 (RW-G) |
| Rail Line | 0.48 (RR-D) | 2.14 (RR-I) | -0.002 (RR-L) | -0.73 (RR-I) |

Loose soils along the HBLR embankment may have shifted in response to the sheet pile deformations resulting in the even greater movements observed the retaining wall and rail line presented in the table above.

## 2.3 Phase I and II Groundwater IRMs

The three IRMs (implemented, Phase I; ongoing, Phase II and Phase III), that are being implemented under PBR authorizations issued by the New Jersey Department of Environmental Protection (NJDEP), use a combination of demonstrated active remediation technologies, including in situ anaerobic bioprecipitation (ISAB) and in situ chemical reduction (ISCR), to achieve the IRM objectives (i.e., to treat Cr and hexavalent chromium [$Cr^{+6}$] concentrations in groundwater).

During Phase I and Phase II IRMs, both injection and extraction wells were used to balance the water table and help spread the injected fluids throughout the groundwater table. During the injection process, some break out or mounding was observed at the injection points. This was typically observed at the location of the injection well where the injection caused the water level to rise to the surface and fluid was observed breaking out or mounding at the surface. On rare occasions, mounding was observed approximately 10 to 20 feet away from the injection well. Mounding was more common in areas where wells were installed in rows, which resulted in a more localized injection zone. The surface mounding is impacted by the injection pressure and volume, as well as the site geology. The fluid will flow through a zone of preferential flow and potentially emerge at the surface. During the Phase I and II IRM phases, extraction wells were located hundreds of feet from the injection wells; due to this distance, the extraction wells are not expected to have a significant impact on mounding effects. Extraction wells will not be used in the Phase III IRM.

# 3. Summary of Site 199 Phase III IRM

As presented in the PBR authorization request for the Phase III IRM, the planned strategy for Site 199 (Target Area 1) includes in situ reagent injections using a permanent well network screened at target depths or direct push reagent injections. Injection of three different types of reagents (molasses and emulsified vegetable oil (EVO), calcium polysulfide (CPS), and FerroBlack®-H) are contemplated for select areas or portions of the shallow, intermediate, and deep injection wells as shown on **Figures 5** through **7**.

The following subsections present the planned strategy for Site 199, including injection flow rates, pressures, and total volumes for the three reagent types and identify potential risks to the HBLR operations posed by the reagent injection activities.

## 3.1 Molasses and Emulsified Vegetable Oil (EVO)

The Site 199 Phase III IRM proposes injection of a molasses and EVO solution at individual wells with flow rates that vary from 0 to 1.5 gpm based on experience gained during the Phase I and II IRMs. Injection pressures will not exceed 25 pounds per square inch (psi) based on the depth of injection and the response of the treatment zones to injection flows and pressures. The following injection volumes are proposed at Site 199 (Target Area 1):

**Proposed Injection Volumes: Target Area 1**

| Water Bearing Zone | Local Maximum Injection Solution Volume (Gallons) | | Number of Injection Wells |
|---|---|---|---|
| | Molasses (0.05%) | EVO (1.5%) | |
| Shallow | 47,000 | 9,000 | 7 |
| Intermediate | 1,400,000 | 230,000 | 24 |
| Deep | 13,000 | 3,000 | 4 |
| Contingency | 1,460,000 | 242,000 | |

## 3.2 Calcium Polysulfide (CPS)

CPS provides ISCR of constituents of concern. A CPS solution may be substituted for up to 50% of the anticipated injection volume of molasses if baseline or treatment monitoring data suggest the presence of areas of elevated $Cr^{+6}$ concentrations (i.e., greater than 1,000,000 micrograms per liter [µg/L]). If employed, the CPS solution will be injected using the same injection flow rates and pressures as molasses.

## 3.3 Potential Risks to HBLR Operations – Molasses, EVO, and CPS

Implementation of the molasses, EVO and CPS injections would pose the following risks to HBLR operations:

- Track fouling during injection well installation – A drill rig will work close to the HBLR retaining wall. If the drill rig tipped over with the mast up, it could cross the track or catenary lines.
- Ground movement during injection well installation – Drilling techniques including sonic drilling may generated ground vibrations that could cause soil movement beneath the retaining wall and tracks.
- Ground movement from groundwater mounding – Injection of the molasses and EVO solution will cause a temporary rise in the water table. If the rise in water table saturates soils that are not saturated by normal water table fluctuations, the soils will consolidate under the changing effective stress as the water table recedes; this may cause settlement of the retaining wall and tracks.

## 3.4 FerroBlack®-H

FerroBlack®-H is a proprietary reagent of Redox Solutions, LLC, and is a reductive, colloidal suspension of soluble and insoluble iron sulfides. In areas planned for FerroBlack®-H treatment, the

reagent will be delivered into the target zones to establish a reducing environment within the zone of influence of the injected material.

Injection wells will be pre-drilled using roto-sonic (sonic) drilling technology. At each location, after logging and photographing the soil to the target depth, the evacuated borehole will be backfilled with hydrated bentonite to seal the borehole wall. A direct push rig will then be used to install probe rods fitted with specialized tips to push through the column. The tool head will be customized for directional injections. Wells will be installed in transects spaced 25 feet on center with three nested well installations completed in each transect. Each boring will have five injection intervals with an injection interval range of 40 to 65 feet. The injected reagent slurry may include up to 54,000 gallons of water and 285,000 pounds of FerroBlack®-H.

The proposed injection flow rates can be up to 280 gpm with injection pressures up to 2,000 pounds per square inch gauge (psig). Based on the existing site geology, it is anticipated that the system will operate at flows of 70 to 200 gpm and pressures of 500 psig realized in the subsurface (not including system pressure losses).

### 3.4.1 Potential Risks to HBLR Operations - FerroBlack®-H

Implementation of the FerroBlack®-H injection would pose the following risks to HBLR operations:

- Track fouling during injection well installation;
- Ground movement during injection well installation;
- Ground movement from groundwater mounding; and
- Changes to the soil structure – High pressure is used to loosen the soil and allow the FerroBlack®-H slurry to permeate the pore space surrounding the injection point. The initial pressure gradient at the injection point may result in critical pore pressure gradients and temporary soil liquefaction. As the slurry flows into the surrounding soils and pressures dissipate, soil heave or expansion may occur. Both the localized liquification and heave may cause retaining wall, catenary structure or track movement.

## 4. Risk Evaluation and Mitigation

Four specific types of risks to the HBLR operations posed by the Site 199 Phase III IRM are identified in **Section 3**. They include:

- Track fouling during injection well installation;
- Ground movement during injection well installation;
- Ground movement from groundwater mounding; and
- Changes to the soil structure.

Each risk is evaluated and mitigation measures are identified in the following subsections.

### 4.1 Track Fouling During Inject Well Installation

Given the proximity of the proposed injection wells and points (for the three proposed reagent types) to the retaining wall and tracks, there is potential for track or catenary line fouling. The track fouling risk can be mitigated by maintaining drill rig masts below the fouling zone. If the rig mast must extend into the fouling zone, then the railroad operator would be notified and a flagger may be

required to direct train traffic during the drilling activities. In addition, measures to ensure the rig is level and properly stabilized with outriggers would be implemented.

Soil borings and monitoring wells have been installed in Site 199 without incident. The track fouling risk does not preclude implementation any of the three reagent injections if proper planning and mitigation measures are in place during the well or injection point installation.

## 4.2 Ground Movement During Injection Well Installation

Sonic drilling techniques that generate ground vibration may be used to install injection wells or points for the three reagent types. As noted above, the loose soils beneath the HBLR are susceptible to vibration-induced movements. However, the ground vibrations caused by sonic drilling are typically much less than those generated by sheet pile installation. If injection wells and points must be installed with sonic drilling, then a vibration monitoring program should be implemented during the well installation to ensure that vibration levels are less than prescribed thresholds where ground movement may occur.

## 4.3 Ground Movements from Groundwater Mounding

The proposed injection volumes for the three reagents are sufficient to generate a groundwater mound. As described above, temporary groundwater mounding beyond normal water table fluctuations may cause settlement of the retaining wall and tracks as the mounded water table recedes.

To determine the potential for the three proposed reagent injection types to create a groundwater mound above normal water table fluctuation and induce settlement, historical water levels were reviewed to establish the fluctuation range. In addition, groundwater modeling simulations were conducted to estimate the extent of the water level mound that would occur from the molasses EVO or CPS injections. These are described in the following subsections.

### 4.3.1 Review of Historical Water Levels

Groundwater levels were measured in the vicinity of the Site 199 beginning in 2004. Discrete water level measurements taken from the shallow wells range from elevation 2.5 feet in the North American Vertical Datum of 1988 (NAVD88) to elevation 13.2 feet (NAVD88). Statistical review of the data in the Site 199 area show that the water level is below elevation 11.2 feet NAVD88 90% of the time.

During 2015 and 2016, a capillary rise study was performed to support the design and use of a capillary break at the Project Area to prevent potentially impacted groundwater from reaching the surface through capillary action (AECOM, 2017). Pressure transducer data collected during the capillary rise study were analyzed to estimate the natural range of water table fluctuations and the water table rise in response to rainfall events. Five wells were selected for this analysis including three near Site 199 that are within sheet piles and two to the southwest, further from Site 199, that are located outside of the sheet piles. The table below shows the minimum, maximum, and range of water levels for each of the five selected wells for the period from June through October of 2016. The range of the water level fluctuation within the wells during this timeframe fluctuated between 1.73 and 4.08 feet with a maximum water level elevation of 9.72 feet NAVD88 and a minimum value of 5.64 feet NAVD88.

**Range of Water Levels**

| Well ID | Inside Sheet Piles | Min Water Level (ft NAVD88) | Max Water Level (ft NAVD88) | Range (feet) |
|---|---|---|---|---|
| 132-P3A-MW104S | No | 6.99 | 9.25 | 2.26 |
| PZ1 | Yes | 5.64 | 9.72 | 4.08 |
| 114-P1C-MW101S | Yes | 6.73 | 8.85 | 2.12 |
| 114-P2B1-MW101S | Yes | 5.96 | 8.65 | 2.69 |
| 137-P3B-MW102S | No | 6.88 | 8.61 | 1.73 |

Note: ft NAVD88 = feet in the North American Vertical Datum of 1988

The water level response to several rainfall events was evaluated by comparing each rainfall event to the corresponding water level rise at each well. The projected baseline water level in the following table reflects the expected water level extrapolated from the trendline of the available dataset. The peak water level is the highest water level measured after the rainfall event. The two wells outside the sheet piles showed 7.14 and 14.33 inches of water table rise for each inch of rainfall. The water table rise within the three wells within the sheet piles, located closer to Site 199, ranged from 12 to 20 inches of rise for each inch of rainfall. Because some runoff gets trapped within the sheet piles, recharge to groundwater in wells within the sheet pile may be higher than what is expected at Site 199. A summary of the water table fluctuations in response to rainfall events is shown in the following table:

**Water Table Fluctuations in Response to Rainfall Events**

| Well ID | Inside Sheet Piles | Projected Baseline Water Level (ft NAVD88) | Peak Water Level Time After Rainfall | Peak Water level (ft NAVD 88) | Increase (inches) | Rainfall (inches) |
|---|---|---|---|---|---|---|
| 132-P3A-MW104S | No | 7.83 | 7/10/2016 7:00 | 8.00 | 2.00 | 0.28 |
| PZ1 | Yes | 6.46 | 7/26/2016 22:00 | 8.09 | 19.54 | 0.99 |
| 114-P1C-MW101S | Yes | 7.40 | 7/26/2016 0:00 | 8.39 | 11.85 | 0.99 |
| 114-P2B1-MW101S | Yes | 6.57 | 7/27/2016 20:00 | 8.18 | 19.34 | 0.99 |
| 137-P3B-MW102S | No | 7.40 | 7/26/2016 7:00 | 8.58 | 14.19 | 0.99 |

Note: ft NAVD88 = feet in the North American Vertical Datum of 1988

Based on the review of the groundwater elevation data, an injection-induced groundwater mound maintained below elevation 11.2 feet NAVD88 would be within the water table fluctuation range and would not cause settlement.

### 4.3.2 Groundwater Modeling – Molasses/EVO and CPS Injections

A numerical groundwater model was created for the Project Area using the United States Geological Survey (USGS) software MODFLOW-USG Transport with the Groundwater Vistas graphic user interface. This model was developed to advance the Phase III IRM design and was used to assess the potential for mounding due to Phase III injections at Site 199. Model simulations were created to evaluate an injection system that would only allow a maximum of 1 foot of mounding (conservative assumption) at the wells to minimize the potential for saturation of fill beneath the light rail tracks which could cause movement (settlement).

The Phase III IRM design for Site 199 includes the following injection wells – four in the shallow water-bearing zone (WBZ), 14 in the intermediate WBZ, and two in the deep WBZ. In addition, during the operation of these injection wells, four injection wells in the intermediate WBZ in Forrest Street would be in operation, as well as (potentially) some select wells along Carteret Avenue.

Model simulations included several scenarios, each evaluating combinations of these injection wells operating concurrently or in series. Each model simulation began with all wells injecting at 0.6 gpm for 90 days. **Figure 8** shows mounding contours for the scenario with only the Site 199 wells in operation, which resulted in a maximum of 2.21 feet of mounding. **Figure 9** shows mounding contours for the scenario with Site 199 and Forrest Street wells in operation, which resulted in a maximum of 2.28 feet of mounding. Based on a simulation of only the selected Carteret wells in operation, the estimated contribution from those wells to groundwater level increase at Site 199 was less than 0.2 feet.

Based on these model simulations (which do not meet the criterion for a maximum of 1 foot of mounding), several additional simulations were performed iteratively, whereby the injection rates were reduced to limit mounding to below 1 foot, while still achieving adequate reagent spread around the injection wells. Through these simulations it was estimated that by reducing the injection rates in all Site 199 wells from 0.6 gpm to 0.3 gpm, the mounding would be reduced to less than 1 foot and adequate reagent spread would be achieved to cover the target areas in the shallow, intermediate, and deep WBZs. **Figure 10** shows mounding contours and reagent concentrations after 90 days with Site 199 wells injecting at 0.3 gpm and Forrest Street wells injecting at 0.6 gpm. **Figure 11** shows mounding contours and reagent concentrations after 90 days with Site 199 wells injecting at 0.3 gpm and Forrest Street and selected Carteret wells injecting at 0.6 gpm. Both of these scenarios satisfy the mounding criteria and adequate reagent concentration spread.

Based on the review of the historical groundwater levels and the groundwater model simulations, the molasses and EVO or CPS injections (at flow rates of 0.3 gpm to 0.6 gpm) would not generate a groundwater mound beyond normal water table fluctuations and would not cause ground movements beneath the HBLR. Groundwater level response to the relatively low injection rates will be gradual so that groundwater monitoring in piezometers screened around the injection zones can be conducted during injection to ensure the mounding is maintained below elevation 11.2 feet NAVD88. If water levels in the piezometers approach this level, then injection can be stopped, or the rate further reduced. A detailed water level monitoring plan should be developed as part of the final design for the EVO or CPS injections.

Given the high injection pressures and flow rates required deliver the FerroBlack®-H slurry, the resulting groundwater level response to the injection could not be simulated with the groundwater flow model. The FerroBlack®-H slurry (54,000 gallons of water and 285,000 pounds of FerroBlack®-H) will be injected over approximately 10 days. The resulting response in groundwater levels is likely to be rapid and could exceed the 11.2 feet NAVD88 threshold. Groundwater level monitoring may not identify elevated groundwater levels in time to shut down the injection and prevent the groundwater levels from exceeding 11.2 feet NAVD88.

### 4.4 Changes to the Soil Structure

The risk of change to the soil structure does not preclude the use of the molasses and EVO or CPS injections. These injections are at sufficiently low flow rates and pressure so that soil pore space and grain structure would not be altered.

The proposed FerroBlack®-H injection (flow rates of 70 to 200 gpm and pressures of 500 psig) will initially loosen the soil around the injection points. Pressure gradients in the pore spaces may become critical (i.e., vertically upward) causing localized soil liquefaction. **Figure 12** shows the stress distribution from the HBLR embankment within the underlying soils. The stress distribution contours (percent of total embankment load developed from Boussinesq theory) shows that soils within the proposed FerroBlack®-H injection zone are supporting the embankment. Localized liquefaction caused by the high-pressure injections would result in embankment settlement.

As the FerroBlack®-H slurry is forced into the pore spaces, soils may expand or shift. Injection pressures may erode and displace fine-grained particles in the treatment zone causing additional heave and soil movement within the soils that are supporting the embankment.

Initial soil movement in response to the injection is likely to be rapid and may continue after injection has stopped. Settlement monitoring along the retaining wall and tracks would be unable to identify problematic ground movements in time stop the injection and halt the movements.

AECOM performed a pilot test to evaluate FerroBlack®-H emplacement through hydraulic fracturing of low-permeability layers at the southeast corner of Site 114 (AECOM, 2019). Tilt meters at the ground surface detected small movements (less than an inch) during the pilot injection. Lithology within the injection zone (low-permeability soils) is not similar to the Site 199 injection zone and the injection methods used in the pilot test (injection of a thin layer of reagent within the low permeable stratum) are not the same as those proposed at Site 199 (injection is a slurry across a three- to five-foot interval).

## 5. Conclusions and Geotechnical Recommendations

Based the review of the Site 199 subsurface conditions, a review of previously observed ground movements, and the evaluation of the potential risks identified for each of the proposed reagent injections, AECOM recommends that the Site 199 Phase III IRM proceed as follows:

- Molasses and EVO or CPS injection and monitoring wells should be installed in a manner that addresses the risks of track fouling. If a drill rig mast needs to extend into the fouling zone, the HBLR operator should be notified and rail operator procedures must be followed.
- If sonic drilling is required to install injection or monitoring wells, then a vibration monitoring plan should be developed and implemented during the well installation.

- A groundwater level monitoring plan should be developed and implemented to ensure the molasses and EVO or CPS injections do not result in groundwater mounding above elevation 11.2 feet NAVD88.
- Initial molasses and EVO or CPS solutions injection rates should be at or less than 0.3 gpm and should be adjusted, as necessary, based on the groundwater level monitoring results. Injections should take place during periods of lower groundwater elevation, if possible.
- Injection of the FerroBlack®-H slurry should not be attempted at Site 199.

## LEGEND

- Model Domain

**Model Boundary Conditions**

- General Head Boundary
- Well Boundary (represents leaking water line)
- Drain Boundary Condition
- Shallow Target Zone
- Injection Well
- Horizontal Flow Barrier (Sheetpile)
- Groundwater Level Increase Contour (0.5 ft Interval)

**Reagent Concentration (parts per million)**

- < 100

## STRATIGRAPHY

**SHALLOW WATER-BEARING ZONE**

- FILL: FINE TO COARSE SAND WITH SILT AND GRAVEL. MAY INCLUDE VARIOUS MATERIALS ASSOCIATED WITH HISTORICAL FILL SUCH AS: CONSTRUCTION SPOILS, DEMOLITION DEBRIS, GARBAGE, INCINERATOR ASH, COAL ASH, SHIP BALLAST, AND INDUSTRIAL WASTE
- DENSE-GRADED AGGREGATE (DGA) FILL: FINE TO COARSE SAND WITH FINE GRAVEL AND SILT

**INTERMEDIATE WATER-BEARING ZONE**

- SAND AND SILTY SAND WITH LENSES OF GRAVEL, SILT, OR CLAY

**DEEP WATER-BEARING ZONE**

- SAND WITH LENSES OF GRAVEL, SILT, OR CLAY
- BASAL TILL (LOWER FACIES OF RAHWAY TILL) REDDISH-BROWN SILTY CLAYS, SANDY SILTS, AND SILTY SANDS WITH SUBROUNDED TO SUBANGULAR FINE TO COARSE GRAVEL AND COBBLES, AND OCCASIONAL INTERBEDDED LENSES OF CLAY, SILT, OR FINE SAND. HARD, DENSE, COMPACT, AND TYPICALLY DRY.
- BEDROCK: STOCKTON FORMATION, LOCKATONG FORMATION, OR DIABASE
- AREA WITH VISUAL OBSERVATIONS OF CCPW, CONSISTING OF COPR, GREEN-GRAY MUD, OR FILL MIXED WITH COPR OR GREEN-GRAY MUD
- FERROBLACK-H AMENDED BACKFILL AREA

NOTES:

1. ELEVATIONS ARE SHOWN IN FT NAVD88.
2. APPROXIMATE ZONE OF INFLUENCE DETERMINED FROM BOUSSINESQ STRESS CONTOURS FOR AN INFINITELY LONG FOUNDATION. B = BASE WIDTH (WIDTH OF EMBANKMENT). P = PRESSURE.

DEFINITIONS:

| | |

# 1.0 Introduction

## 1.1 Purpose

The Field Sampling Plan/Quality Assurance Project Plan (FSP/QAPP) for operations at the PPG Industries, Inc. (PPG) residential and non-residential chromium sites, including associated perimeter air monitoring, in Hudson County, New Jersey, was developed by AECOM Environment (AECOM) to comply with the New Jersey Department of Environmental Protection (NJDEP) quality assurance (QA) requirements for remedial investigations (RI). The purpose of the FSP/QAPP is to assure reliable monitoring data by serving as the instrument of control for field and analytical activities associated with the project. Stated or referenced within the FSP/QAPP are the analytical methods, sampling procedures, Quality Assurance policies, Quality Control (QC) criteria, and reporting requirements that must be followed by all prime and subcontractor personnel when carrying out their assigned responsibilities on the project.

This document is intended to be an organic document that is updated as required and will be modified as necessary during the performance of activities. This FSP/QAPP was prepared in accordance with the July 19, 1990 Administrative Consent Order (ACO) between the State of New Jersey and PPG Industries, Inc., and the NJDEP Technical Requirements for Site Remediation (New Jersey Administrative Code [N.J.A.C.] 7:26E-2.2 *et. seq*.). This FSP/QAPP will also be utilized during execution of the remedial activities related to the Judicial Consent Order (JCO) as filed on June 26, 2009.

The FSP/QAPP was prepared in accordance with the requirements and methods described in the NJDEP *Technical Requirements for Site Remediation* (N.J.A.C. 7:26E *et. seq.*, November 4, 2009, date last amended April 19, 2010), *Field Sampling Procedures Manual* (August, 2005, last updated April 30, 2009), *Alternative Ground Water Sampling Techniques* (July 1994), *Field Analysis Manual* (July 1994) and N.J.A.C. Chapter 9D *Well Construction, Maintenance, and Sealing of Abandoned Wells Drilling Regulations and Requirements* (April 2, 2007), as guidance. Remedial investigation results will be compared to New Jersey's *Remediation Standards* (N.J.A.C. 7:26D *et. seq*., November 2009) for soil delineation purposes for non-chromium compounds. The most stringent (non-residential) chromium soil cleanup criteria (CrSCC) of 20 mg/kg for hexavalent chromium, and the most stringent (residential) soil cleanup criteria of 120,000 mg/kg for trivalent chromium, will be utilized for soil delineation purposes pursuant to the *Chromium Soil Cleanup Criteria* (NJDEP, September 2008). Groundwater results will be compared to the *Ground Water Quality Standards* (N.J.A.C. 7:9C), last amended November 4, 2009.

The FSP/QAPP is the standard by which field and laboratory procedures must be performed and the standard against which activities will be audited. In the event that the FSP/QAPP must be changed to include a new procedure or modify an existing procedure, the procedure discussed in **Section 3.0** of the FSP/QAPP will be used to document the change.

## 1.2 Project Background

PPG Industries, Inc., owned and operated a chromate chemical production facility encompassing approximately 16.6 acres located on Garfield Avenue in the City of Jersey City, County of Hudson, New Jersey.

On or about September 1, 1963, PPG ceased operations at the chromate chemical production facility. These operations had resulted in the generation of chromate ore processing residue (COPR) that was distributed by third parties as fill material for use in certain construction and development projects in Hudson County, New Jersey.

The chromate ore processing residue was used for the backfilling of demolition sites, preparation for building foundations, construction of tank berms, roadway construction, the filling of wetlands and other construction and development-related purposes.

The JCO requires the investigation and if necessary, the remediation of chromate chemical production waste (CCPW) at residential properties within the vicinity of the PPG sites. Perimeter air monitoring will be conducted during various ground intrusive remedial phases at the Garfield Avenue site (PPG Site 114) for protection of residents and the community. The remaining PPG residential and non-residential chromium sites are designated by the ACO. This FSP/QAPP will augment the individual work plans and report submittals developed for on and off-site work.

## 1.3 Data Quality Objectives

Data Quality Objectives (DQOs) are qualitative and quantitative statements that specify the quality of data needed to accomplish the project objectives. The design for each sampling program will be based on USEPA's DQO guidance (USEPA, 2000), a multi-step, iterative process that ensures that the type, quantity, and quality of environmental data used in decision-making is appropriate for its intended application. This process is summarized below:

- State the problem;
- Identify the decision;
- Identify inputs to the decision;
- Define the study boundaries;
- Develop a decision rule;
- Specify decision error limits; and
- Optimize the study design.

The field collection efforts at the non-residential sites will generate data to be used for a variety of purposes, including but not limited to site characterization, evaluation of alternatives, engineering design, risk assessment, and potential responsible party (PRP) determination. Therefore, the sampling and analysis programs incorporate the following QA elements:

- A sampling program designed to obtain sufficient data to determine levels of constituents in media of interest;

- The use of sample collection and handling procedures that will ensure the representativeness and integrity of the samples;
- An analytical program designed to generate definitive data of sufficient quality and sensitivity to meet the project objectives; and
- Data deliverables that will allow verification and validation of the data and reproducibility of the reported results.

## 1.4 Project Schedule

Project schedules for each site are site-specific and will be presented in the site-specific work plans or other individual report submittals for each site.

# 2.0 Project Organization

A Project Management Team has been established that consists of three primary classifications: the Principal-in-Charge, Project Managers, and the Field Operations Leader. Responsibilities of the management team, and supporting staff, are described in **Section 2.1**.

## 2.1 Management Responsibilities

The roles and responsibilities each for program position that will participate in projects associated with this FSP/QAPP are summarized below. Personnel assigned to these positions are provided in **Table 2-1**.

AECOM:

**Principal-In-Charge (PIC):** The Principal-in-Charge (PIC) works closely with PPG Industries, Inc. and is responsible for managing contractual agreements between AECOM and PPG. The PIC will also have the responsibility for reviewing major deliverables to ensure compliance with the FSP/QAPP requirements.

**Project Managers:** Project Managers (PMs) will be designated on a site-by-site basis and will be responsible for daily coordination of the project, management of the project team, and the overall success of the project. The Project Manager will review reports and all correspondence prior to submission, and will act as overall technical coordinator. The Project Manager will maintain budget and schedule; track invoices, purchase orders, subcontracts; and set project goals and objectives according to proposal and client-authorized changes as they arise.

**Field Operations Leader:** The Field Operations Leader (FOL) is directly responsible for sampling quality control. It is the FOL's responsibility to mobilize the proper equipment, ensure that sampling procedures are implemented properly, that field control samples are collected as required, maintain chain of custody, and complete the required documentation. The FOL has full authority over logistical aspects of sampling in the field and the authority to implement minor changes to sampling plans to accommodate field conditions.

**Site Supervisor:** The site supervisor has the overall responsibility and authority to direct work operations at the job site according to the work plans. The Site Supervisor may also serve as a Task Leader or other role.

**Task Leader:** Task Leaders have the responsibility for supervising subcontractors, and for overseeing the collection of soil and groundwater sampled. A geologist or hydrogeologist will be the Task Leader for drilling and well construction operations, and has the responsibility for supervising the drilling subcontractor during the collection of soil samples and grab-groundwater samples, and installation of monitoring wells, and for classifying soil samples in the field. The Task Leader will ensure that field engineering and geological data is in accordance with currently accepted

professional standards and that wells are installed in accordance with the FSP/QAPP, work plans and other report submittals.

The Task Leader will have the direct responsibility to ensure that soil and groundwater sampling activities are performed in accordance with the FSP/QAPP, work plans and other report submittals. The task leader reports directly to and is supervised by the FOL. The task leader will communicate with the FOL and report any conditions that may require changes in field activities or procedures.

The Task Leader or another AECOM representative may be designated by the Site Safety Officer (SSO) to perform as the SSO's field representative, and will report directly to the SSO to ensure that procedures outlined in the Health and Safety Plan (HASP) are followed.

**Sampling and Health and Safety Technicians:** Sampling Technicians are responsible for implementing sampling procedures as described in the FSP/QAPP, work plans and other report submittals. Sampling Technicians do not have the authority to change the sampling plan. Sampling Technicians may also serve as Health and Safety (H&S) Technician, and will report directly to the SSO's representative to ensure that the proper H&S precautions are taken. There will be an H&S Technician on-site for all activities. The H&S technicians' responsibilities are further outlined in the site-specific HASP and work plans.

**Regional Safety, Health & Environment Manager (RSHEM):** The AECOM RSHEM is the individual responsible for the preparation, interpretation and modification of the Health and Safety Plans (HASPs) as needed and will serve as the primary Health and Safety resource for the program.

**Database Manager:** The Database Manager will be responsible for the development and management of the groundwater, soil, and geologic databases. Additional support by trained administrative staff will be available as needed.

**GIS Manager:** The GIS Manager will be responsible for maintaining the geographic information systems for the program, and directing the production of GIS drawings and data presentation.

**Data Validation Manager:** The Data Validation Manager will act as the data review supervisor.

**Project Quality Assurance Officer (QAO):** The QAO will be responsible for maintaining compliance with AECOM's internal and project specific standards and practices for Quality Assurance. The project QAO will maintain and implement the FSP/QAPP.

**Engineering Manager:** The Engineering Manager will manage and delegate tasks related to evaluation of remedial options and implementation of remedial actions.

**On-Site Health & Safety Coordinators:** Each of the Task Leaders identified in **Table 2-1** will be in charge of coordinating health and safety issues on site and maintaining health and safety documentation for the duration of time each is on-site. They will apprise the Field Operations Leader of matters regarding health and safety. However, decisions pertaining to health and safety will be the responsibility of the RSHEM, with input from the Site Safety Officer, Site Supervisor and Task Leaders, as appropriate. These personnel will be responsible for coordinating field staff, maintaining budget and schedule, as well as the development of detailed internal work plans and schedules. Each

will be in charge of coordinating health and safety issues on-site and maintaining health and safety documentation during their time on-site.

PPG Industries, Inc.:

**Director, Environmental Affairs:** The PPG Director, Environmental Affair is responsible for overall contract execution and PPG program management.

**Project Manager, Environmental Remediation:** The PPG Project Managers are responsible for monitoring field activities, assisting in contract execution, management of individual site projects, and coordinating with various contractors on technical work execution.

NJDEP:

**Manager, Site Remediation:** The primary NJDEP representative is responsible for review and approval of submittals. JCO Team:

**JCO Site Administrator:** The Site Administrator is appointed by the Courts under the terms of the JCO and is responsible for establishing the Master Schedule, coordination of JCO activities, holding meetings with stakeholders, and hiring experts and consultants to assist him in JCO oversight, financial management of the JCO Fund, and other related tasks as dictated by the JCO.

**JCO Site Administrator Project Manager:** The Site Administrator Project Manager is responsible to assist the Site Administrator in his duties.

**Technical Consultant:** The Technical Consultant is hired by the Site Administrator under the terms of the JCO and provides technical support to the Site Administrator and NJDEP, and other tasks as dictated by the JCO.

## 2.2 Laboratory

The analytical laboratory contractors supporting the standard analytical work for the non-residential and residential chromium site remedial activities are Accutest Laboratories, Inc. (Accutest), and Test America (formerly Severn Trent Laboratories, Inc. (STL)). The geotechnical laboratory supporting the geotechnical analyses will be GeoTesting Express, Inc. Analysis of hexavalent chromium on air filters will be performed by Galson Laboratories. Analyses of air filters for particulates ($PM_{10}$) will be performed by the AECOM laboratory in Harvard, MA. Measurements for Dissolved Oxygen, pH,

temperature, turbidity, specific conductance, and oxidation/reduction potential (ORP) in the field will be performed by AECOM personnel.

All laboratories utilized for this program will be NJDEP-certified laboratories and hold current certifications for parameters of interest listed in **Appendix D** (where appropriate). **Table 2-2** provides contact and certification information for the participating laboratories.

**Table 2-2 Laboratory Information**

| Laboratory | Laboratory Contact | NJDEP Certification No. | Analytical Role |
|---|---|---|---|
| Accutest Laboratories<br>Fresh Ponds Corporate Village, Building B<br>2235 Route 130<br>Dayton, NJ 08810 | Matt Cordova,<br>Director of Client Services<br>Phone: 732.329.0200<br>e-mail: matt@accutest.com | 12129 | Laboratory support for chemical analysis of soil and water samples |

## 2.3 Field Responsibilities

Task Leaders for continuing investigation and remedial activities, will be responsible for locating sample points (e.g., wells), ensuring adequate sample containers are available for sampling personnel, making sure that the required samples are collected and proper sampling techniques are used, ensuring that the appropriate documentation is completed, and the samples are properly preserved, packaged, and shipped to the appropriate laboratories. Task Leaders will receive copies of field notes and documentation from Field Team members and will review these notes. Deficiencies

in the field notes will be reported by the Task Leaders to the project QAO and Field Team authors. Field notebook authors will revise the field notes as appropriate. Task Leaders and on-site representatives will also be responsible for subcontractor management while AECOM subcontractor personnel are onsite and ensuring that tailgate health and safety briefings are conducted for compliance with the HASP.

The Field Team members' responsibilities will include collecting field samples, collecting personnel and perimeter air monitoring samples, conducting field measurements, and documentation of all activities pursuant to this FSP/QAPP, work plans, AECOM Standard Operating Procedures (SOPs), and applicable NJDEP regulation and guidance. Field Team members will submit a copy of field documentation to the appropriate Task Leader, and will revise notes as necessary based on the Task Leader's quality assurance review.

### 2.3.1 Personnel Training

AECOM and subcontractor personnel working on this program will be properly trained and qualified individuals. Prior to the commencement of work on the site, personnel will be given instructions specific to this project, covering the following areas:

- Organization and lines of communication and authority;
- Overview of the field investigation activities;
- QA/QC considerations;
- Documentation requirements;
- Decontamination requirements; and
- Health and safety considerations.

Training of field personnel will be provided by the AECOM Project Manager, AECOM Task Leaders, Project QAO, and/or any other qualified designee. Federal regulations found in Title 49 of the Code of Federal Regulations (49 CFR) Part 172.702 require that each employer whose employees work with hazardous materials (as defined in sections 49 CFR 171 and 172) must train each of its hazmat employees. "Hazmat employees" include those who prepare the packages for shipping, prepare, sign or review the paperwork, load trucks, drive the vehicles or unload or receive the hazardous materials.

A hazmat employee who performs any of these functions may not perform the function unless he or she has been trained in the requirements of hazardous materials (generally: identification, classification, labeling, marking, placarding, packaging, etc.) that apply to that function. It is the duty of each hazmat employer to comply with the applicable requirements of this subchapter and to ensure that each hazmat employee has received the appropriate training. AECOM employee(s) will have the New Jersey Department of Transportation (NJDOT) Hazardous Materials Transportation Certification pursuant to 49 CFR 172.704. Only personnel knowledgeable and trained in the shipment of hazardous or dangerous goods will be responsible for the shipment of hazardous materials.

# 3.0 Changes to Project Plans

The following procedure provides a means for controlling and documenting changes to the approved FSP/QAPP or site-specific work plans and changes during field activities or related to changes in accepted methods. The objective of the process is to maintain the level of QA/QC provided in the original review and approval process.

## 3.1 Changes or Additions

If non time-critical changes to a FSP/QAPP or site-specific work plan are required, the requesting party will initiate a request for change by editing the existing procedure and indicating the proposed changes by underlining the altered portions of the FSP/QAPP, work plans or other report submittals. The revision will be submitted with a cover letter (which includes the timeline for implementation of the change) to PPG and subsequently NJDEP for review, comment, and/or approval. Changes or additions required by NJDEP will be addressed by PPG based on written comments by NJDEP. Upon acceptance or approval of the revision by PPG and NJDEP, the change will be added to the appropriate section of the project planning document. Depending upon the complexity and extent of modifications, changes may be incorporated by marking the revised pages of the document with the word "revised" with the revision number and date placed in the lower right-hand corner. Extensive changes which result in resubmission of the entire document will be noted as a revision number for the document.

If time critical changes which could impact the overall project schedule (Master Schedule) are indentified, AECOM will implement a procedure for rapid notification of key parties (AECOM Project Manager and Principal-In-Charge, NJDEP's Technical Consultant [Weston] and PPG via direct contact (phone or electronic mail). This will be followed by written documentation of the issue identified, proposed solution, and proposed schedule revisions to the Site Administrator. Following agreement on actions and approval of changes, the existing FSP/QAPP or work plan will be modified as needed. Revised pages or, if necessary, a complete, revised version of these documents will be prepared and distributed to all parties who received the original documents. Any schedule changes or revisions would also be documented in the Progress Report in accordance with 74.e and 74.f. of the ACO.

## 3.2 Changes or Additions to Laboratory Services

In the event that an additional laboratory subcontractor is required to handle the project load or there is a need to add additional analyses to the SOPs for the laboratory, a request will be made in writing to the other party. The letter will document the reason for the change, indicate any new analytical procedures to be used, present all pertinent laboratory SOPs, present the laboratory organization along with resumes and include a schedule for implementation as applicable. The requesting party will forward the letter to the other party for review, comment, and/or approval. Upon approval by both parties, the change or addition will be implemented. Appropriate correspondence documenting the acceptance of the change or addition of the analysis, along with supporting documentation, will be added as an appendix to the FSP/QAPP.

Requests for revisions or additions will be transmitted through the NJDEP Case Manager (if originating from NJDEP) or Mr. Brian McGuire or Mr. Mark Terril. (if originating from PPG) to the AECOM PIC, Mr. Robert Falotico or AECOM Program Manager, Scott Mikaelian

## 3.3 Field Changes or Additions

Because time critical changes or additions to the FSP/QAPP or site-specific work plan may be needed in order to accommodate field conditions or respond to findings obtained in the field, a mechanism to accommodate such changes has been established. These changes or additions may be initiated by either NJDEP or AECOM and PPG through the use of the following procedure:

1. Notification: The requesting party makes contact with the other party to request and discuss the change and a schedule for implementation. Persons to be contacted in addressing field changes are the AECOM PM and PIC, Technical Consultant (Weston), and PPG representative(s).

2. Field Sign-off: Following internal discussion, if both parties orally agree to the change or addition, it will be implemented according to the agreed upon schedule. Oral requests for field changes and agreement on field changes will be documented in the site log book and will require sign-off by both parties in the field log prior to implementation.

3. Project Manager Sign-off: The requesting party must complete a field change request form (**Appendix A**) and submit it to the other party within 72 hours to document written approval of the change.

4. Revision to the FSP/QAPP: All approved field changes will be followed up by formal written changes to the FSP/QAPP, unless the changes are site-specific. Site-specific changes will be documented in the appropriate site-specific report.

# 4.0 Quality Assurance Objectives

The overall QA objective is to develop and implement procedures for field sampling, chain of custody, laboratory analysis, and reporting that will provide results that are legally defensible in a court of law. Specific procedures for sampling, chain of custody, instrument calibration, laboratory analysis, reporting of data, internal QC, audits, preventative maintenance of field equipment, and corrective action are described in other sections of this FSP/QAPP. The purpose of this section is to address the specific objectives for accuracy, precision, completeness, representativeness, and comparability. These terms are described below.

## 4.1 Precision

### 4.1.1 Definition

Precision is a measure of the degree to which two or more measurements are in agreement.

### 4.1.2 Field Precision Objectives

Field precision is assessed through the collection and measurement of field duplicates at a rate of one duplicate per twenty field samples. Precision will be measured through the calculation of relative percent difference (RPD). The equation for this calculation is presented in **Section 5.2.1** of this FSP/QAPP. The objectives for field precision RPDs are 30% RPD for aqueous samples and $\leq$50% RPD for soil, chip, masonry, and air particulate samples. Co-located samples will be collected to assess the precision of air particulate measurements. Field duplicates will not be collected for wipe samples or hexavalent chromium in air.

### 4.1.3 Laboratory Precision Objectives

Precision in the laboratory is assessed by calculating the RPD for duplicates. The equation for this calculation is presented in **Section 5.2.1** of this FSP/QAPP. Matrix Spike/Matrix Spike Duplicate (MS/MSD) samples will be used to evaluate the precision of organic analyses. Laboratory duplicates as well as MS and/or MSD samples will be used for inorganic analyses; blank spike and/or blank spike duplicate samples will be used to assess laboratory precision for the determination of hexavalent chromium collected on air filters. Precision objectives will be the statistical control limits, or those specified in the method, whichever are more stringent.

## 4.2 Accuracy

### 4.2.1 Definition

Accuracy is the degree of agreement between the observed value and an accepted reference value.

### 4.2.2 Field Accuracy Objectives

The achievement of accurate data in the field will be addressed through the use of sampling procedures that minimize bias, the calibration of field instruments, and adherence to sample holding

times and preservation requirements. Accuracy in the field will be evaluated through the use of trip blanks and/or field blanks. These blanks should contain no target analytes above the reporting limit.

### 4.2.3 Laboratory Accuracy Objectives

Laboratory accuracy will be expressed as percent recovery and will be determined through the analysis of matrix spikes, surrogates, and laboratory control samples. The equation that will be used to calculate percent recovery is included in **Section 5.2.2** of this FSP/QAPP. Laboratory accuracy objectives limits will be the statistical control limits, or those specified in the method, whichever are more stringent.

## 4.3 Completeness

### 4.3.1 Definition

Completeness is a measure of the amount of valid data obtained from a measurement system compared to the amount that was expected to be obtained under normal conditions. "Normal conditions" are defined as the conditions expected if the sampling plan were implemented as planned.

### 4.3.2 Field Completeness Objective

Field completeness will be measured on the basis of (1) the number of valid field measurements and (2) the number of valid samples collected. The equation for completeness is presented in **Section 5.2.3** of this FSP/QAPP. The objective for field completeness for this project is greater than 90%.

### 4.3.3 Laboratory Completeness Objectives

Laboratory completeness will be measured by the number of valid measurements obtained compared to the number of valid samples submitted. The equation for calculating completeness is presented in **Section 5.2.3** of this FSP/QAPP. The completeness objective for the laboratory is greater than 90%.

## 4.4 Representativeness

### 4.4.1 Definition

Representativeness expresses the degree to which data accurately and precisely represents a characteristic of a population, parameter variations at a sampling point, a process condition, or an environmental condition.

### 4.4.2 Measures to Ensure Representativeness of Field and Laboratory Data

Representativeness is a qualitative parameter which is dependent upon the proper design of the sampling program and proper laboratory protocol. The rationale of the sampling program is discussed in the site-specific work plan. Representativeness will be satisfied by ensuring that the work plan is followed, proper sampling techniques are used, samples are appropriately preserved, proper analytical procedures are followed, and holding times of the samples are not exceeded. Representativeness will be included as a QA measure during the yearly Project QA audits.

Sampling protocols (discussed in **Section 6**) have been developed to assure that samples collected are representative of the media. Field handling protocols (e.g., storage, handling in the field, and

shipping) have also been designed to protect the representativeness of the collected samples. Proper field documentation will be used to establish that protocols have been followed and that sample identification and integrity have been maintained.

## 4.5 Comparability

### 4.5.1 Definition

Comparability expresses the confidence with which one data set can be compared to another.

### 4.5.2 Measures to Ensure Comparability of Field and Laboratory Data

The extent to which existing and planned analytical data will be comparable depends on the similarity of sampling and analytical methods. The procedures used to obtain the planned analytical data, as documented in this FSP/QAPP, are expected to provide comparable data. Any changes in procedure or QA objectives, however, may affect data comparability.

When comparing data, it is important to compare data collected under the same set of conditions. Seasonal trends, depth of sample collection, analytical protocol, stream flow during sample collection, and any other sampling/analytical variables must be taken into account when comparing data sets.

Comparability will be maximized by: (1) the use of Project Operating Procedures (POPs) and SOPs throughout the project; (2) the recording of data in a standardized format; (3) the use of standard methods; (4) conducting confirmatory sampling and analysis when using alternative sampling and analysis methodologies; and (5) reporting of data in appropriate, consistent units.

## 4.6 Level of Quality Control Effort

### 4.6.1 Field Measurement

The field measurement equipment will be calibrated required under the methodologies specified in **Section 11** of this FSP/QAPP and the individual work plan(s). SOPs and POPs for the use of field instrumentation also contain detailed calibration requirements.

### 4.6.2 Laboratory Analysis

The level of QC effort provided by the laboratory will be equivalent to the level of QC effort required under the methodologies specified in **Section 12** of this FSP/QAPP. Each sample set processed as a batch by the laboratory will include a method blank, a measure of analytical accuracy such as a blank spike or matrix spike, and a measure of analytical precision such as a laboratory or matrix spike duplicate. Laboratories will adhere to all quality control procedures required in the analytical SOPs specified in **Appendix D**.

In accordance with the quality assurance requirements of the recently amended N.J.A.C. 7:26E-2.1(a)7, “The person responsible for conducting the remediation shall ensure that hexavalent chromium analysis of aqueous and nonaqueous samples is conducted as follows: i. Measure the pH and Eh of each sample, not just the quality control sample, with the pH and Eh data included and plotted in the full data deliverables using the graph in USEPA SW-846 Method 3060A incorporated herein by reference, as amended and supplemented; and ii. Use a site sample for the quality control

analyses so the reduction/oxidation effects of the site matrix can be properly evaluated using USEPA SW-846 Method 3060A." The NJDEP certified laboratories that will perform the hexavalent chromium analysis are aware of these requirements. These requirements will also be included in the technical terms and conditions which are part of the laboratory purchase order in order to ensure compliance.

# 5.0 Data Assessment Procedures

## 5.1 Field Measurements

Field data will be reviewed by the AECOM Field Operations Leader and Task Leader for compliance with the Work plan, FSP/QAPP, and SOPs/POPs as applicable. Precision, accuracy, and completeness will be evaluated based on the methods and equations described in **Sections 4.1, 4.2, and 4.3**.

## 5.2 Laboratory Data

Laboratory analytical results will be assessed for compliance with precision, accuracy, completeness, and sensitivity requirements as described in the following sections.

### 5.2.1 Precision

AECOM will review the nonconformance summaries reported by the laboratories, which include RPD measurements outside laboratory QC limits by analyte group.

AECOM expects that the precision of laboratory analysis will be assessed by comparing the analytical results between MS/MSD samples for organic analysis, and laboratory duplicate analyses and MS/MSD samples for inorganic analysis. The RPD will be calculated for each pair of duplicate analysis using the following equation:

$$\%\ RPD = \frac{(S - D)}{(S + D)/2} \times 100$$

where S = original sample data
D = duplicate sample data

### 5.2.2 Accuracy

AECOM will review the nonconformance summaries reported by the laboratories which include monitoring of recovery measurements based on laboratory QC limits by analyte group. The accuracy of laboratory results will be assessed for compliance with the criteria established in **Section 4.2** of this FSP/QAPP using the analytical results of method blanks, trip blanks, field blanks, and MS/MSD samples. The percent recovery (%R) of matrix spike samples will be calculated using the following equation:

$$\%\ R = \frac{(A - B)}{C} \times 100$$

where A = the analyte concentration determined experimentally from the spiked sample,
B = the background level determined by a separate analysis of the unspiked sample, and
C = the amount of the spike added.

### 5.2.3 Completeness

The completeness of laboratory analytical results will be assessed by the laboratory for the amount of data required in **Section 4.3** of this FSP/QAPP. The completeness will be calculated using the following equation.

$$Completeness = \frac{ValidDataObtained}{TotalPlannedData} \times 100$$

### 5.2.4 Sensitivity

The laboratory will monitor the data quality through constant instrument performance and that instrument sensitivity will be monitored through the use of method blanks, calibration check samples, etc., in accordance with the methods listed in **Appendix D** of this FSP/QAPP. Method detection limits will be calculated according to 40 CFR Part 136 Appendix B.

As required in the *Technical Requirements for Site Remediation* at N.J.A.C. 7:26E-2.1(a)8, samples that will be used for determining compliance will be analyzed using a method with adequate sensitivity to accurately measure to the applicable remedial standard. Detection limits will be at or below applicable *Remediation Standards (*N.J.A.C 7:26D*),* last revised November 4, 2009*, or Soil Cleanup Criteria,* last revised May 12, 1999 (for trivalent and hexavalent chromium), Table 1 from the NJDEP guidance document *Development of Site-Specific Impact to Ground Water Soil Remediation Standards using the Soil-Water Partition Equation*, December 2008 (revised), *and* the *Ground Water Quality Standards (*N.J.A.C. 7:9C Appendix Table 1) adopted by reference as Ground Water Remediation Standards. **Tables 5-1 and 5-2** provide a comparison of the laboratory reporting limits with the applicable NJDEP practical quantitation levels (PQL) and remediation standards for the soil and aqueous analytes of interest. The detection limits and action limits for the air monitoring program will be specified in the specific air monitoring work plan.

# 6.0 Field Operations

The standard sampling procedures to be used for the PPG residential and non-residential chromium sites, and perimeter air monitoring are described in this section. All sample collection and field screening will be conducted in accordance with the current versions of the NJDEP *Field Sampling Procedures Manual* (August 2005), the NJDEP *Technical Requirements for Site Remediation* (November 2009), applicable AECOM SOPs/POPs), and accepted practices. SOPs and POPs for all significant field activities are presented in **Appendix B**. All samples will be handled in a manner consistent with the sample container, preservation, and holding time requirements specific to the analytical and data quality requirements of the investigation.

All samples collected during the field investigation will be analyzed by NJDEP-certified laboratories. The laboratories will adhere to the United States Environmental Protection Agency (USEPA) protocols for sample preparation and analysis dictated by the requested analytical method.

Full laboratory data deliverables, as detailed in Appendix A of the NJDEP *Technical Requirements for Site Remediation* (November 2009) will be submitted for all hexavalent chromium and hexavalent chromium associated analytical data (pH, Eh, sulfides, etc.). The full laboratory data deliverables will consist of the following:

- three electronic copies of the laboratory data package on CD in Adobe portable document format (pdf),
- one paper copy of the laboratory data package,
- three electronic copies of the analytical data using the format NJDEP's 1999 *Electronic Data Interchange Manual*,
- and one electronic copy of the analytical data in the EQuIS four-file format, as modified by AECOM.

Reduced laboratory data deliverables, as detailed in Appendix A of the NJDEP *Technical Requirements for Site Remediation* (November 2009), will be submitted for all other analytical data (ex. metals, volatile organic compounds [VOCs], etc…). The reduced laboratory data deliverables will consist of the following:

- one electronic copy of the full, validatable laboratory data package on CD in Adobe pdf will be submitted,
- three electronic copies of the analytical data using the format NJDEP's 1999 *Electronic Data Interchange Manual*, and
- one electronic copy of the analytical data in the EQuIS four-file format, as modified by AECOM.

Details are provided in this section for both field measurement activities and sample acquisition. Details are also provided for:

- Equipment cleaning and decontamination;
- Drilling and monitoring well installation;
- Sample storage and handling; and
- Documentation.

In addition to the requirements described in the above protocols, the following general requirements apply to all sampling activities:

- Whenever possible, samples will be collected in order of least to most contaminated, so that risks of systematic contamination are minimized.

  Samples designated for laboratory analysis will be collected from the liner and placed in appropriate laboratory pre-cleaned containers (after homogenization, if appropriate). Per Section 6.9.2, Means of Sample Collection, of the *NJDEP Field Sampling Procedures Manual* (August 2005) the order in which analytical samples should be collected is as follows:

  1. VOC (prior to soil sample homogenization);
  2. Total organic halogens (TOX)
  3. Total organic carbon (TOC)
  4. Semivolatile organic compounds (SVOCs)
  5. Extractable petroleum hydrocarbons (EPH)
  6. Polychlorinated biphenyls (PCBs)
  7. Total metals
  8. Dissolved metals (groundwater only)
  9. Phenols
  10. Cyanide
  11. Chloride
  12. Preserved inorganics
  13. Non-preserved inorganics

  When several wells with known or suspected contamination will be sampled, the least contaminated well should be sampled first, and the wells then sampled in order of increasing contamination.

- Additional sample locations will be co-located when necessary to obtain additional sample volume for the required analyses from each depth interval or sample location. The samples will be thoroughly homogenized prior to filling the sample bottles, except for samples collected for volatile organics analysis.
- Wherever possible, sampling equipment will arrive at the Site pre-cleaned and will be dedicated to one sample location on-site. Where not practical, field decontamination will be conducted in accordance with **Section 9**.
- Water and soil samples requiring chemical preservation will be placed in pre-preserved containers supplied by the laboratory.
- Sample containers and blank water will be obtained from the analytical laboratories which will provide properly cleaned and preserved (where required) sample containers. The vendor-prepared bottles will be prepared according to USEPA protocol as described in Specification and Guidance for Contaminant-Free Sample Containers, EPA 540/R-93/051. The laboratories will also prepare analyte-free blank water to be used for field blanks. Care will be taken to ensure that blanks are prepared using only water supplied by the laboratory that will perform the analysis. In general, a single laboratory will be responsible for the analysis of samples collected at a single location. For air samples, a blank filter will be submitted with field samples; the filter will be from the same manufacturing lot as that used for sample collection.
- Field changes to site-specific work plan(s), either by AECOM field personnel or NJDEP field personnel, are permissible only when made in strict accordance with field change policies described in **Section 3**.
- Outer gloves will be changed between sampling locations.
- Air monitoring will be conducted in accordance with the HASP. Field instruments for air monitoring will include a photoionization detector (PID), hydrogen sulfide ($H_2S$) portable, hand-held analyzer, and an aerosol/dust monitor.

## 6.1 Soil and Building Materials Investigation

Drilling and soil sample collection will be supervised by the Task Leader who will be an AECOM geologist/hydrogeologist. Drilling, sample collection, well construction and well/boring abandonment will be conducted in accordance with N.J.A.C 7.9D. A driller licensed by the State of New Jersey will be in charge of all drilling operations. Drillers shall be required to comply with OSHA 1910.120. Drilling and soil sampling procedures in the applicable POP(s) are attached in **Appendix B (POP Nos. PPG 005 and PPG 006).**

Soil samples will be screened for VOC in the field shortly after collection using an instrument equipped with a PID. The equipment will be issued through a formal equipment tracking system and operated by trained personnel in accordance with manufacturers' recommendations. All field measurement equipment will be maintained to ensure that measurements obtained are accurate and defensible.

All samples will be placed in pre-cleaned containers for transport to the laboratory. Soil samples for VOC will be transferred directly from the sample collection tool to containers prepared by the laboratory in accordance with the NJDEP *Field Sampling Procedures Manual* (August 2005) (refer to

applicable POP(s) in **Appendix B (POP No. PPG 005**). VOC sample collection utilizing EnCore® or similar sampling devices will reduce the potential for VOC loss during sample collection and will result in lower reporting limits comparable to the impact to groundwater soil remediation standard. VOC samples will be collected using an EnCore® or similar sampling device and promptly shipped to the laboratory to permit freezing or analysis within 48 hours of collection.

Soil samples for all other parameters will be homogenized prior to placing in the containers. Homogenization will be performed in a stainless-steel bowl per the applicable POP(s) in **Appendix B (POP No. PPG 005)**. Building materials samples will be placed in containers without homogenization. Prior to homogenization, soils will be field screened with a PID using the applicable POP(s) in **Appendix B (POP Nos. PPG 004 and PPG 005)**.

In accordance with N.J.A.C. 7:26E-3.6(a)4, all soil samples to be analyzed for volatile organics shall be collected as follows:

i. A bulk sampling device that will collect an intact core (for example, splitspoon) shall be used to minimize contaminant loss during sampling; and

ii. Each core shall be screened with a properly calibrated direct reading instrument equipped with a photoionization detector (PID), flame ionization detector (FID), or other suitable instrument capable of detecting the contaminants pursuant to N.J.A.C. 7:26E-2.1(b) to select samples of volatile organics analysis using the following criteria:

(1) If field measurement readings are detected above background:

(A) The coring shall be extended until either background readings are achieved, groundwater is encountered, or bedrock is encountered; and

(B) An undisturbed sample from the six-inch interval registering the highest field measurement reading shall be collected, at a minimum, using the appropriate sample collection method and sampling device for volatile organics analysis pursuant to the requirements specified in N.J.A.C. 7:26E-2.1(a)4; or

(2) If all intervals register the same field measurement reading or all field measurement readings do not exceed backgrounds:

(A) The coring shall be extended to groundwater, bedrock, or 10 feet, whichever is encountered first; and

(B) One undisturbed sample at a minimum, from the six-inch interval at the bottom of the soil boring shall be collected, using the appropriate sample collection method and sampling device for volatile organics analysis pursuant to the requirements specified in N.J.A.C. 7:26E-2.1(a)4; and

iii. Contaminants that cannot be detected with field-screening instruments shall be sampled in accordance with the requirements at N.J.A.C. 7:26E-3.4(a).

### 6.1.1 Utility Protection

Prior to conducting any intrusive operations, existing drawings and other available documentation will be reviewed to evaluate whether potential conflicts with underground utilities exist. New Jersey One Call will be notified by the drilling contractor at least three and not more than ten business days prior to the start of drilling in each off-site area.

If any doubt exists regarding the potential presence of subsurface utilities, a professional utility locating service will be retained to conduct surveys to clear proposed drilling locations. A variety of techniques are available to locate utilities, including ground penetrating radar, electromagnetic conductivity, radio frequency, audio frequency, and passive electric. The efficacy of each technique is dependent on the material used to construct the utility, type of utility, number and type of nearby utilities, and many other factors. As such, it is common practice to use more than one utility locating technique. The requirements for utility location and appropriate techniques will be determined once available information is gathered and evaluated.

Soil boring, sampling, and monitoring well locations will be adjusted to avoid underground and overhead utilities. As an added precaution, vacuum boring to a depth of four feet or to the expected invert depth of the deepest utility at any given soil boring or well location may be conducted. However, if vacuum boring is required at certain locations, collection of shallow soil samples for laboratory analysis in the vacuumed zone will still be undertaken from the sidewall area of the vacuumed zone to ensure that shallow surface soil samples will be collected at all proposed off-site investigation locations.

### 6.1.2 Direct-Push Drilling and Soil Sampling

Direct-push methods (Geoprobe® and similar systems) of soil sampling utilize a hydraulically-powered percussion drilling machine to drive hollow soil samplers into the subsurface to obtain soil samples. The equipment and hydraulics used in the drilling machine are generally mounted on a vehicle to provide both mobility around the jobsite and a stable drilling platform. A POP for direct-push drilling is included in **Appendix B (POP No. PPG 005)**.

Geoprobe® sampling systems typically utilize the Macro-Core sampler, which is a 45-inch long, 1.5-inch diameter hollow steel sampling barrel, lined with a disposable factory-clean acetate liner. It is the Macro-Core which is driven into the ground for collection of soil samples. This method works best in stable subsurface environments where borehole collapse is not a significant issue.

Where borehole instability is anticipated (e.g., “running sands”), sampling can also be conducted using a dual tube sampling system. This system is similar to the Macro-Core except that the liner (in this case PVC) is withdrawn but the steel outer casing remains in place until the last sample is collected and the borehole grouted to prevent borehole collapse.

Once a sample is collected, the liner is cut with a knife by the driller (per the project HASP). Following liner cutting, the soil sample will be field screened with a calibrated PID, if required. Sample recovery will be determined by the geologist/hydrogeologist using a folding rule or tape measure. Any portion of the split-spoon contents which are not considered part of the true sample (heaved soils, borehole scrapings, etc.) will not be included in the measurement.

Due to anticipated variations in sample recovery, thickness of various strata identified in the recovered sample, and the number of analyses proposed, sample collection precedence as described below will be used to collect soil samples. Samples will be collected using this precedence until no additional material is available for the sampling interval. If additional sample volume is needed to complete the analyte suite required, sample volume will be collected from the six-inch interval directly above or below the target interval, whichever is most similar in terms of geology and field observations.

Samples designated for laboratory analysis will be collected from the liner and placed in appropriate laboratory pre-cleaned containers (after homogenization, if appropriate). Sample order precedence is discussed above in **Section 6.0**. Sample handling is discussed in **Section 10.0**.

### 6.1.3 Split-Spoon Sampling

Soil samples obtained during hollow-stem auger or mud-rotary drilling will be collected using a split-spoon sampler (refer to POP No. PPG 005 in **Appendix B**). Split-spoon sampling devices are constructed of steel and are most commonly available in lengths of 18 and 24 inches and inside diameters of 1.5 to 3 inches. Typically, the 1.5-inch diameter sampler is used; however, larger diameter samplers may be used if large volumes of soil are required for analytical testing.

The split-spoon consists of a tubular body with two halves that split apart lengthwise, a drive head on the upper end with a ball-check valve for venting, and a hardened steel cutting shoe at the bottom. The soil sample enters the split-spoon through the cutting shoe as the device is driven into the ground. A replaceable plastic or metal basket is often inserted into the shoe to assist with retaining samples. Once the sampler is retrieved, the drive head and cutting shoes are removed and the split-spoon halves are then separated, revealing the sample.

The drilling subcontractor will lower the split-spoon into the borehole. The sampler is generally driven into the ground using a 140-pound hammer with a vertical free drop of 30 inches, although a down-hole hammer or hydraulic drivers may be utilized as an alternative.

The number of blows required for every 6 inches of penetration will be recorded on the boring. Blow count information is used as an indicator of soil density for stratigraphic logging purposes. Once the split-spoon has been driven to its fullest extent, or to refusal, it will be removed from the borehole. Refusal is defined as 50 blows for six inches or less of penetration.

The split-spoon will be immediately opened upon removal from the casing/auger/borehole. The open sampler shall then be field screened with a calibrated PID, if required. Sample recovery will be determined by the geologist/hydrogeologist using a folding rule or tape measure. Any portion of the split-spoon contents which are not considered part of the true sample (heaved soils, borehole scrapings, etc.) will not be included in the measurement.

Samples designated for laboratory analysis will be collected from the liner and placed in appropriate laboratory pre-cleaned containers (after homogenization, if appropriate). Sample order precedence is discussed in **Section 6.0**. Sample handling is discussed in **Section 10.0**.

### 6.1.4 Soil Sampling Beneath Residential Slabs

During completion of field activities, it may become necessary to collect soil samples from beneath concrete slabs in residential buildings. Soil sampling beneath residential slabs will be conducted following the applicable POP(s) in **Appendix B** (POP No. PPG 005). Prior to collection of the samples, utility protection measures consistent with **Section 6.1.1** will be implemented to ensure the concrete at the proposed sampling location is free of utilities. After the sampling location has been cleared for utilities, the drilling contractor will utilize a concrete core drill to create an opening in the slab of sufficient size to allow for collection of the soil samples. Upon completion of sampling activities, the drilling contractor will repair the opening with concrete.

### 6.1.5 Air Sampling

The AIRMETRICS MiniVol™ portable air sampler will be used for the integrated sampling of airborne particulates ($PM_{10}$) and hexavalent chromium on 47 mm filters. Two separate MiniVol™ samplers will be used; for the collection of $PM_{10}$ the sampler will be configured to draw air at 5 liters/minute through a 10 micron particle size separator (impactor) then though a 47 mm pre-weighed filter. A similar configuration will be used for the collection of hexavalent chromium with the exception that no particle size impactor is required and the flow rate will be set at 3.5 liters/minute. Filters for $PM_{10}$ and hexavalent chromium will be recovered and shipped under chain-of-custody to off-site laboratories for analysis.

Additional on-site air measurements will include the use of a direct reading real-time MIE DataRAM Analyzer or TSI DustTrak Aerosol Monitor or equivalent for the determination of $PM_{10}$ which will be used as a surrogate for continuous monitoring of hexavalent chromium, metals, and polyaromatic hydrocarbons (PAHs). Total VOC (TVOC) concentrations associated with ground intrusive activities will be monitored through the use of RAE portable PID. If an elevated TVOC level is detected at one of the fixed air monitoring sites, a gas chromatograph fitted with an automatic injection feature will monitor for benzene, toluene, ethylbenzene and xylenes (BTEX). As needed, handheld measurements for hydrogen sulfide will be made using the Arizona Instrument Jerome Model 631X Hydrogen Sulfide portable analyzer or equivalent.

Specific procedures for these field instruments are contained in SOP Nos. PPG-017 and PPG 020 in Appendix B.

### 6.1.6 Feasibility Study

Material which is tentatively identified as Green-Gray Mud or Chromite Ore Processing Residue (COPR) but cannot be confirmed to be one of these materials through other techniques such as visual, magnetic or similar tests will be subjected to hydrochloric acid testing using the procedure described in POP PPG 015. Green-Gray Mud is expected to contain percent levels of calcium; COPR may contain significant levels of calcium as well. The field test described in POP PPG 015 will involve dropwise addition of 1:1 Hydrochloric Acid to a sample of the suspected material, if calcium or other carbonate salts/minerals are present foaming or effervescence should occur. However, as noted in the POP, this test is not specific to calcium and should be used in conjunction with other observations to assist in the identification of materials containing Green/Gray Mud and COPR.

In order to document that representative samples are obtained for testing of proposed remediation procedures, samples taken from a predetermined grid will be field screened for grain size using a series of sieves. In addition, soil color and the presence/absence of COPR nodules or paste-like material will be documented; photographs will be used as appropriate to further document the nature of the sample. POP PPG 016 describes the specific procedures which will be used to document the condition of field samples collected for assessment of remediation options.

## 6.2 Quality Control Samples

QC samples collected during field activities will consist of trip blanks, field blanks, field duplicates, matrix spike, and matrix spike duplicate samples. The procedures for collection of specific sample matrices are discussed in the applicable POPs in **Appendix B** (POP Nos. PPG 005, PPG 008, PPG 010, PPG 011, PPG 012, PPG 013, PPG 018, and PPG019) and below. A description of the QC samples is provided below:

- **Field Blanks:** Field blanks are analyzed to check for procedural contamination at the site that may cause sample contamination. Field blanks will be prepared by routing analyte free deionized/distilled water (provided by each laboratory performing the sample analysis) through sampling equipment after equipment decontamination and before field sample collection. The blank water quality supplied by each laboratory will meet the requirements stated in Section 2.5.4 of the NJDEP *Field Sampling Procedures Manual* (August 2005). The appropriate laboratory water will be used to collect the field blanks depending on the analysis and the laboratory performing the analysis. Thus, field blanks associated with analyses to be performed by a designated laboratory will only be collected using the deionized/distilled water supplied by the designated laboratory. In addition, if specific water is provided by the laboratory for a specific analysis then only that water will be used to collect the associated field blank.

  Field blanks will be preserved in the same manner as samples (**Appendix C**). For air and wipe sampling, field blanks will be collected using filters and wipes from same lot number as those used for sampling. For this FSP/QAPP, field blanks will be collected at the frequency specified in Table 6-1 and analyzed for all applicable target parameters as specified in **Table 6-1**.

  **For the non-aqueous matrix**, for sampling events lasting more than one day, field blanks associated should be performed at a rate of 10% of the total number of samples collected throughout the event for all parameters sampled that day. If collection of 10% of total number of samples will result in the collection of more than 1 Field Blank per day, this is not necessary per the NJDEP FSPM (2005).

  **For the aqueous matrix**, field blanks must be performed at a rate of one per day for all parameters sampled that day.

- **Trip Blanks:** Trip blanks are used to assess the potential for contamination of samples due to VOC contaminant migration during sample shipment and storage. Each laboratory performing volatile organic analysis will prepare trip blanks by filling sets of 40-milliliter (ml) vials with analyte free deionized water, sealing the vials with septum-lined caps (allowing no headspace or entrapped air bubbles). The vials will then be kept with the sample cooler

from the time the sampling kit leaves the laboratory until it is returned from the field. The blank water quality supplied by each laboratory will meet the requirements stated in Section 2.5.4 of the NJDEP *Field Sampling Procedures Manual* (August 2005). The trip blanks prepared by a designated laboratory will only accompany samples being delivered to that designated laboratory. In general, a single laboratory will be responsible for all analyses associated with a specific location. According to the *NJDEP Field Sampling Procedures Manual* (August 2005), trip blanks are not required for the non-aqueous matrix. Trip blanks will be required at a frequency of one set per cooler in which aqueous VOC samples are shipped (**Table 6-1**). Trip blanks will be analyzed for VOC only.

- **Field Duplicates:** Field duplicates are analyzed to check for sampling and analytical reproducibility. Duplicate samples will be collected by alternately filling sample bottles from the source being sampled. Field duplicates will not be collected for wipe samples. Co-located samplers will be used for the collection of field duplicates for the $PM_{10}$ analysis. Field duplicates for air, soil, aqueous, chip, and masonry samples will be collected at the frequencies specified in **Table 6-1**.
- **Matrix Spike Samples:** Matrix spikes provide information about the effect of the sample matrix on the preparation and measurement methodology. Matrix spikes for organic and inorganic analyses are performed in duplicate and (referred to as MS/MSD samples). MS/MSD samples will be prepared by the laboratory according to their SOPs, as applicable to the method. A matrix spike/laboratory duplicate analysis may be substituted for an MS/MSD for inorganic parameters (if allowed by the method) at the same frequency as the MS/MSD. MS/MSDs will not be collected for wipe and air samples; blank spikes and blank spike duplicates will be used for these analyses. MS/MSD soil, aqueous, chip, and masonry samples will be collected at the frequencies specified in **Table 6-1**.

## 6.3 Borehole Abandonment

Unless a well is to be installed, boreholes will be abandoned by grouting in accordance with N.J.A.C 7.9D.

## 6.4 Location Measurements

The locations of all new borings and other sample collection points will be measured using standard surveying techniques or using GPS. The locations and elevations of all new monitoring wells will be measured by a New Jersey State licensed surveyor in accordance with NJDEP requirements. Latitude and Longitude will be measured to the nearest 1/10 of second (NAD 83) and to the New Jersey State Plane Coordinates (NAD 83) to the nearest 1 foot. A permanent reference mark will be made on the top of the riser (cap off), and the elevation (NAVD 88) will be surveyed to the nearest 1/10 foot. Surveyors shall be required to comply with OSHA 1910.120. All surveying and reporting of location information will be in compliance with the requirements of N.J.A.C. 7:26E-3.13(c)3v.

## TABLE 6-1 QUALITY CONTROL SAMPLE SUMMARY

| Matrix [1] | Analyses [1] | Quality Assurance Samples | Sampling Frequency | Criteria |
|---|---|---|---|---|
| AIR | Chromium (Total and Hexavalent) | Field Blank | 1/day from same lot number as sample filters | <MDL [8] |
| | Particulates ($PM_{10}$) | Field (Blind) Duplicate (co-located) | 1/20 samples (5% of total) or minimum of 1/week | RPD < 50% |
| WIPES | Chromium [4] (Total and Hexavalent) | Field Blank | 1/day from same lot number as the sample wipes | <RL [2] |
| SOIL, CHIP, CONCRETE, SWEEP, MASONRY (including TCLP and/or SPLP, as applicable) | TCL VOCs<br>TCL SVOCs<br>TCL PCBs<br>TAL Metals<br>Hexavalent Chromium [4]<br>EPH<br>Phenols<br>Cyanide | Field Blank | Either 1/day or 10% of the total number of samples collected, but not more than 1/day | < RL [2] |
| | | Field (Blind) Duplicate | 1/20 samples (5% of total) | RPD < 50% |
| | | MS/MSD | 1/20 samples (5% of total) | See method [3] |
| | Wet Chemistry [5] | Field Blank | Either 1/day or 10% of the total number of samples collected, but not more than 1/day | < RL [2] |
| | | Field (Blind) Duplicate | 1/20 samples (5% of total) | RPD < 50% |
| | Geotechnical [6] | Field (Blind) Duplicate | 1/20 samples (5% of total) | RPD < 50% |
| | Waste Characteristics [7] | | | |

## TABLE 6-1 QUALITY CONTROL SAMPLE SUMMARY (continued)

| Matrix [1] | Analyses [1] | Quality Assurance Samples | Sampling Frequency | Criteria |
|---|---|---|---|---|
| AQUEOUS | TCL VOCs | Trip Blank | 1/cooler | < RL [2] |
| | | Field Blank | 1/day | < RL [2] |
| | | Field (Blind) Duplicate | 1/20 samples (5% of total) | RPD < 30% |
| | | MS/MSD | 1/20 samples (5% of total) | See method [3] |
| | TCL SVOCs<br>TCL PCBs<br>TAL Metals<br>Hexavalent Chromium [4]<br>EPH<br>Phenols<br>Cyanide | Field Blank | 1/day | < RL [2] |
| | | Field (Blind) Duplicate | 1/20 samples (5% of total) | RPD < 30% |
| | | MS/MSD | 1/20 samples (5% of total) | See method [3] |
| | Wet Chemistry [5] | Field Blank | 1/day | < RL [2] |
| | | Field (Blind) Duplicate | 1/20 samples (5% of total) | RPD < 30% |
| | Waste Characteristics [7] | Field (Blind) Duplicate | 1/20 samples (5% of total) | RPD < 30% |

Notes:

[1] - These are proposed matrices and analytes, refer to the RIWP for the specific matrices and analytes.

[2] - Refer to Tables 5-1 and 5-2 for the analyte specific RL.

[3] – Refer to the specific analytical methods for the MS/MSD QC Criteria.

[4] – Hexavalent chromium analysis includes Eh and pH analysis on every sample.

[5] – Wet Chemistry analyses may include BOD, CEC, COD, TDS, TSS, TOC, TOX, Alkalinity, Chloride, Ferrous iron, Nitrate, Nitrite, Phosphate, and Sulfide.

[6] – Geotechnical analyses may include moisture content, permeability, specific gravity, grain size, bulk density, Atterberg limits, and unconfined compressive strength.

[7] – Waste Characteristic analyses may include ignitability, reactivity, moisture content, and corrosivity.

[8] - Refer to the specific air monitoring work plan.

# 7.0 Groundwater Investigation

Soil boring investigation methodologies are described previously in **Section 6.0**. The following section details the well construction, development, and groundwater sampling methodologies.

## 7.1 Well Construction

Wells will be constructed by the drilling contractor at the direction of the Site geologist/hydrogeologist. Wells will be constructed in accordance with N.J.A.C 7.9D typically using two-inch (nominal) Schedule-40 PVC riser and screen. Wells installed below the meadow mat (or equivalent elevation, where there is no meadow mat) will be double cased using a six-inch (minimum) nominal diameter steel pipe as the outer casing. The outer diameter of the borehole will be a minimum of four inches larger than the well riser or outer casing. Double cased (or telescoping) wells will be advanced into the meadow mat (intermediate wells) or deeper confining layer (deep wells). The outer casing will be installed into the confining or semi-confining geological unit and grouted in place. Drilling to the target depth will proceed following a minimum period of 24 hours so that the grout has had sufficient time to set.

In boreholes where a shallow water-bearing zone is encountered above a deeper water bearing zone, casing will be installed to prevent downward migration between the water-bearing zones in accordance with N.J.A.C. 7.9D. The casing will be installed into the confining or semi-confining unit; or where absent to a sufficient depth to prevent migration between the water-bearing zones. The annular space between the casing and borehole, as well as the annular space between water-bearing zones, will be grouted. The grout will be allowed to set for a minimum of 24 hours prior to further advancement of the borehole. In accordance with the NJDEP *Field Sampling Procedure Manual* (August 2005), installation of well couplets (e.g., shallow and deep) and well triplets (e.g., shallow, intermediate and deep) will be installed in separate boreholes since grout is less likely to invade well intakes (screens) if the wells are installed in separate boreholes. Care will be taken to assure that any confining unit between aquifer zones is not breached without providing adequate protection of underlying/overlying aquifers.

Well screens will be machine-slotted (0.010- to 0.020-inch slots), and will be of a length suitable for the particular use. Sand pack will be installed to an approximate height of two feet or greater above the top of the screen. An approximate one-foot thick bentonite seal will then be placed above the sand pack and the remainder of the well annulus will be grouted with a Portland cement and bentonite mixture. Specific well construction procedures are presented in POP PPG 006 in **Appendix B**.

## 7.2 Well Development

Not sooner than 24 hours after completion, all wells will be developed to remove fines and minimize the effects of drilling on the water quality. Pumping will be the preferred method for developing the monitoring wells. When recharge is adequate, the monitoring well will be surged (by surge block or by raising and lowering the pump along the screened interval) and pumped using one of the following: a

submersible pump or a surface centrifugal pump. Bailing may be used to surge the well and remove sediment if recharge is inadequate to use a submersible pump to develop the monitoring well.

Well development water will be contained in 55-gallon drums or tanks for waste classification and disposal. The determination of groundwater disposal for off-site wells will be made on a case-by-case basis by the Site hydrogeologist, with PPG approval. Well development procedures are presented in POP PPG 007 in **Appendix B**.

## 7.3 Groundwater Sampling Procedures and Equipment

To ensure that each groundwater sample collected is representative of the conditions at that location, and that the sample is neither altered nor contaminated by the sampling and handling procedures, AECOM will conduct all sampling as per the NJDEP *Field Sampling Procedure Manual* (August 2005), and applicable AECOM SOPs and POPs. All groundwater samples will be handled in a manner consistent with the sample container, preservation, and holding time requirements specific to the analysis requirements of this investigation (refer to Appendix C of the *Field Sampling Procedures Manual*, August 2005). Groundwater sampling procedures are presented in POP PPG 008 in **Appendix B**.

Field instruments that will be utilized in the groundwater remedial investigation will include water level indicators (Solinst® or equivalent), oil/water interface probes, water quality meters (Horiba U-22 or equivalent), and/or PIDs (as required). All field measurement equipment will be maintained to ensure that measurements obtained are accurate and defensible. The equipment will be issued through a formal equipment tracking system and operated by trained personnel in accordance with manufacturers' recommendations.

### 7.3.1 Groundwater Sampling Program

All groundwater samples will be collected in accordance with the NJDEP *Low Flow Purging and Sampling Guidance* (December 2003). Prior to initiating the groundwater sampling program, synoptic groundwater elevation measurements will be collected. A PID and/or a gas monitor (if required by the HASP) will be used to screen the well headspace immediately after the cap is removed. Then, from the survey mark at the top of the well casing, the depth to water and the total depth of the well will be measured using an appropriate water level gauging meter.

Permanent monitoring wells installed with a screened interval of 10 feet will be sampled at two locations within the well. The locations will be at five-foot intervals within the screen, in accordance with the NJDEP *Low Flow Purging and Sampling Guidance* (December 2003). Groundwater sampling logs will be completed in the field as per New Jersey Technical Requirements and will include measurements of field parameters ( i.e., temperature, pH, conductivity, dissolved oxygen, turbidity, and oxidation-reduction potential). Groundwater quality parameters will be measured and recorded at timed intervals prior to and during purging to evaluate the stabilization of water quality parameters prior to sampling as directed in applicable guidance documents.

#### 7.3.1.1 Low-Flow Purging and Sampling

Low-flow purging and sampling will be accomplished using a peristaltic pump (submersible or bladder pumps will be utilized for samples for VOC analysis) as described in POP PPG 008 in **Appendix B**.

Groundwater will then be purged from the well at rates between 0.1 liters per minutes (L/min) and 0.5 L/min) through dedicated polyethylene tubing (Teflon© or Teflon©-lined tubing will be utilized for samples for VOC analysis) attached to a flow-through cell and in-line water quality meter.

Water quality indicator parameters (WQIPs) will be collected once water fills the in-line cell at a minimum of 5-minute intervals. Water quality parameters will be monitored for stabilization. Stabilization will be defined when three consecutive water quality readings are within:

| Field Measurement | Stabilization Requirement |
|---|---|
| Temperature | ±3% |
| pH | ±0.1 Standard Units |
| Specific Conductivity | ±3% |
| Turbidity | ±1 Nephelometric Turbidity Units (NTU)* |
| Dissolved Oxygen (DO) | ±10% |
| Oxidation-Reduction Potential (ORP)/Eh | ±10 mV |
| * Turbidity readings must stabilize to ± 10% for turbidity (if greater than 1 NTU). Because metals are a primary concern at this site and metals analyses are strongly influenced by the presence of suspended solids in the sample, special attention will be paid to turbidity measurements. Typically, turbidity stabilization needs to occur first. The target value shall be < 10 NTUs. After turbidity stabilization is attained the remainder of parameters will be evaluated for stabilization. After four hours of purging, samples will be collected regardless of whether WQIPs have stabilized. | |

Water levels will also be monitored during purging and the purge rate will be adjusted (where possible) to minimize drawdown (not greater than 0.3 feet). Upon stabilization of water quality parameters, the water line will be severed prior to the in-line water quality meter and samples will be collected directly from the pump/tubing. AECOM is certified (NJ Lab Certification # 12995) to collect Dissolved Oxygen, pH and temperature measurements in the field. AECOM's Lab Certification for field measurement of conductivity, turbidity and ORP is pending upon NDJEP approval of certification. Laboratory-supplied sample bottleware will be filled directly from the tube starting with VOC vials. The order of sample collection will be:

1. VOC
2. TOX
3. TOC
4. SVOC
5. EPH

6. PCBs
7. Total Metals
8. Dissolved Metals (groundwater only)
9. Phenols
10. Cyanide
11. Chloride
12. Preserved inorganics
13. Non-preserved inorganics

Non-VOC samples may not be collected before VOC samples. When several wells will be sampled of known or suspected contamination, the least contaminated well should be sampled first, and the wells then sampled in order of increasing contaminant concentration for that parameter, as long as VOCs are collected prior to non-VOC parameters.

## 7.4 Hydraulic Conductivity Testing

In-situ permeability (rising and falling head or "slug") tests will be conducted in selected wells to estimate in-situ lateral variability thereof. Permeability data will be used to estimate the average linear velocity of the groundwater, and to evaluate whether separate flow regimes may exist as a result of lithologic differences.

Time-drawdown data will be collected by instantaneously displacing a volume of water and recording the change in water level as the well recovers. Water will be displaced using a solid slug. Slug size will be selected to displace enough water to ensure a valid test. Where the static water level is found above the screened interval, a falling-head test and a rising-head test will be performed. Where the static water level is in the screen, two rising head tests will be performed, as displacement of water into the unsaturated screened zone introduces error into testing results. Water levels will be recorded automatically with pressure transducers and an electronic data logger. The time-drawdown data will be analyzed in the office utilizing the appropriate analytical method. Duplicate test results will be compared to determine the precision of the method and then, if appropriate, averaged to give a more accurate value. Field procedures for performing slug tests are presented in POP PPG 009 in **Appendix B**.

## 7.5 Quality Control Samples

QC samples collected during field activities will consist of trip blanks, field blanks, field duplicates, and/or MS/MSDs (described in **Section 6.2**) as appropriate to the matrix and analytical method. The procedures for collection of these samples are discussed in **Section 6.0**. Frequencies of collection for QC samples are specified in **Table 6-1**.

# 8.0 Building Component Sampling

Building component sampling provides information on monitoring surficial contamination and is intended for non-volatile species. Four types of sampling methods for collecting building components are presented as follows:

1. **Chip Sampling:** Applicable for obtaining samples of porous material (e.g., concrete and brick) on flat surfaces (e.g., floors). The procedure is presented in POP PPG 010 in **Appendix B**.

2. **Wipe Sampling:** Applicable mostly for collecting samples from the surface of non-porous materials (e.g., painted walls, glass, or metal). The procedure is presented in POP PPG 011 in **Appendix B**.

3. **Concrete Core Sampling:** Applicable for collecting samples of concrete floor slabs and foundations. The procedure is presented in POP PPG 012 in **Appendix B**.

4. **Scrape/Sweep:** Applicable for collecting scrape and sweep samples from all types of surfaces. The procedure is presented in POP PPG 013 in **Appendix B**.

# 9.0 Decontamination and Waste Management Procedures

All equipment, vehicles, and personal protective equipment (PPE) potentially exposed to hazardous materials will be decontaminated prior to removal from the Site.

Equipment in contact with samples will be decontaminated prior to use to ensure sample integrity. Wherever possible, pre-cleaned, disposable or dedicated equipment will be utilized. All other sampling equipment used in the field investigations will be cleaned before and after sample collection using a three-part decontamination procedure. Cleaning of equipment is performed to prevent cross-contamination between samples and to maintain a clean working environment for all personnel. Detailed decontamination procedures are presented in POP PPG 014 in **Appendix B**.

Although it is preferred that all non-aqueous field sampling equipment is either laboratory cleaned, wrapped, and dedicated, it may be necessary to decontaminate in the field using more than one method. Decontamination of equipment in the field that is not dedicated or disposable will be conducted in general accordance with POP PPG 014 found in **Appendix B** of this FSP/QAPP. The following modifications to the decontamination POP PPG 014 in **Appendix B** will be made:

Eight-Step Decontamination Process:

A solvent rinse and acid rinse steps of the full 8-step decontamination process will not be performed during field decontamination. Under typical field conditions, the 3-step decontamination process consisting of a laboratory grade glassware detergent (i.e., Alconox®) and tap water scrub to remove visible contamination followed by a generous tap water rinse and a final rinse using distilled and deionized (ASTM Type II) water. If visual contamination persists, or gross contamination is suspected, additional decontamination procedures will be required (steps 4 through 8 below dependent upon the analysis required.

The field sampling equipment cleaning and decontamination procedures are as follows:

1. Laboratory grade glassware detergent plus tap water wash to remove all visible particulate matter and residual oils and grease;

2. Generous tap water rinse;

3. Distilled and deionized (ASTM Type II) water rinse;

4. 10% nitric acid rinse (trace metal or higher grade $HNO_3$ diluted with distilled and deionized (ASTM Type II) $H_2O$)*

5. Distilled and deionized (ASTM Type II) water rinse*

6. Acetone (pesticide grade) rinse**

7. Total air dry or pure nitrogen blow out**

8. Distilled and deionized (ASTM Type II) water rinse**

*Only if sample is to be analyzed for metals.
**Only if sample is to be analyzed for organics.

All sampling equipment decontaminated via this procedure must be wrapped and/or sealed during storage and prior to use. If visual contamination persists, or gross contamination is suspected, additional decontamination procedures will be required.

In the field, decontamination should be carried out over a container and the residual liquid material must be properly disposed. Decontamination wastes must be disposed in accordance with current NJDEP policy (see Chapter 2 of the *Field Sampling Procedure Manual* (August 2005), Section 2.4.5.7, *Disposal of Development, Purge, Pump Test and Decontamination Water*). Where possible, only dedicated and disposable materials will be used for sample collection to minimize the need for on-site full decontamination.

Decontamination of drilling equipment will be performed by the drilling subcontractor. AECOM will provide the drilling subcontractors with a copy of all the applicable POP(s) . Subcontractors will be overseen to ensure that decontamination is completed in accordance with POP PPG 014 and NJDEP *Field Sampling Procedures Manual* (August 2005).

## 9.1 Management of Waste Liquids

Waste liquids are managed directly by PPG in accordance with the Resource Conservation and Recovery Act (RCRA), Department of Transportation (DOT) requirements, NJDEP requirements for the disposal of installation, development, purge, pumping test and decontamination waters (Section 2.4.5.7 of the *Field Sampling Procedures Manual* (August 2005)) and all applicable laws and regulations. All purge water and waste decontamination fluids will be containerized. Waste liquids are periodically (less than 90 days after generation) transported off-site for proper management as a hazardous waste.

Waste liquids generated at off-site parcels will be placed in 55-gallon drums. The 55-gallon drums will either be transported to the Site 114 Drum Storage Area by the drilling contractor utilizing a rack truck, or will be secured at the off-site parcel for subsequent disposal.

## 9.2 Management of Drill Cuttings

Drill cuttings and other hazardous solids are managed directly by PPG in accordance with RCRA and DOT requirements, NJDEP requirements for the disposal of drill cuttings (Section 2.4.5.6 of the *Field Sampling Procedures Manual* (August 2005)) and all applicable laws and regulations. All drill cuttings will be containerized in DOT-approved 55-gallon drums and transported on a daily basis (minimum) to the on-site drum storage area. Drummed waste is periodically (less than 90 days after generation) transported off-site for proper management as a hazardous waste. Drill cuttings generated at off-site parcels will be placed in 55-gallon drums. The 55-gallon drums will either be transported to the Site 114 Drum Storage Area by the drilling contractor utilizing a rack truck, or will be secured at the off-site parcel for subsequent disposal.

# 10.0 Documentation and Chain-of-Custody

Documentation of custody is one of several factors that are necessary to document the proper handling of samples A sample is considered to be in a person's custody if:

- It is in the actual possession of an authorized person;
- It is in the view of an authorized person, after being in his/her actual possession;
- It was in the actual physical possession of an authorized person and then was locked up to prevent tampering; or
- It is in a designated and identified secure area.

## 10.1 Field Custody Procedures

### 10.1.1 Field Procedures

The field sampling personnel along with the Task Leader will be personally responsible for the care and custody of the samples until they are transferred or dispatched properly.

All sample containers will be labeled with a unique sample identifier that will consist of an alphanumeric sequence. Any other pertinent information regarding sample identification will be recorded in the field logbooks and/or on sample log sheets. Soil samples will be identified by the boring number followed by the depth of the sample below ground surface. Groundwater samples will be identified by the well number.

Labels will be completed prior to or during the sampling event for each sample. Labels will be completed with the site name, sample ID, sample collection date and time, analysis requested, and preservative (if any) and will be initialed by the sample collector. Labels will be water resistant, and will be completed using waterproof ink.

All relevant information will be transferred to a laboratory-supplied chain of custody (COC) form and signed by the individual responsible for the sampling.

Copies of the COC and field documentation will be supplied to the FOL or his/her designee on the same day as the sampling event. The FOL will review field activities to determine whether proper custody procedures were followed during the fieldwork and will decide if additional samples are required. The FOL will notify the project QAO of any deficiencies encountered during the review of documentation and will provide a copy of the reviewed/corrected COC to the Database Manager.

### 10.1.2 Field Notebook/Documentation

Field notebooks will provide the means of recording the data collecting activities performed. As such, entries will be described in as much detail as possible so that persons going to the Site could reconstruct a particular situation without reliance on memory.

Field notebooks will be bound, numbered, field survey books or notebooks. Field notebooks will be maintained by the Task Manager until they are archived. Each notebook will contain the notebook number, project identification, “return to” information, and project start and end dates. Entries into the notebook will include the Project name and number, date, start-time, weather, summary and purpose of planned field activities, and the names of all sampling team members present. The names of visitors to the Site (including subcontractors), the times and dates of their arrival and departure, and the purpose of their visit will also be recorded in the field notebook.

Content of the field notebook will include, but not be limited to, measurements made and samples collected, descriptions of sampling locations, sample collection times and depths, calibration information for field equipment, etc. Information recorded in the field notebook may be transferred to AECOM standard logs used to record and present field data. These logs may include:

- Geologic/Soil boring logs;
- Well construction logs;
- Well development logs;
- Groundwater purge and sample logs;
- Water level and product thickness records;
- COC forms; and
- Environmental sample logs.

Logs will include entries in every blank, with appropriate use of the abbreviations NA (not applicable) and NR (not recorded). All "NR" entries should be accompanied by an explanation. All entries will be recorded in waterproof ink or marker, and signed and dated by the person making the entry. No erasures will be made. If an incorrect entry is made, the information will be crossed out with a single strike mark, the correct entry recorded, and the change initialed and dated by the person making the correction.

Special visual observations and detection of odors shall be indicated in the field book. However, careful attention shall be given when attributing the source or substance of the observations.

A photographic log will also be maintained (when applicable) by AECOM field personnel. Field documentation of each photograph will be recorded in the field notebook and will contain a description of the object and field of view being photographed, type and lens size (if applicable) of camera, direction faced, frame number, time and date the photograph was taken, identity of photographer, and indication of scale or scale reference. The reference number assigned to the photograph and described in the log will be written on the back of the photograph and/or the file name of the electronic version will be saved with the reference number. Copies of the photographic logs will be filed in a central location in the AECOM Piscataway, New Jersey office. Detailed field documentation procedures for the Recording of Field Data are presented in POP PPG 001 in **Appendix B**.

### 10.1.3 Transfer of Custody and Shipment Procedures

Samples will be packaged and shipped according to POPs PPG 002 and PPG 003 in Appendix B. Samples will be accompanied by a properly completed COC form. At the time the sample possession is transferred, the individuals relinquishing and receiving will sign, date, and note the time on the record. This record documents the transfer of custody of samples from the sampler, to another person, to a mobile laboratory, to the permanent laboratory, or to/from secure storage locations.

Minimum information recorded on the COC record in addition to the signatures and dates of all custodians will include the following information in the appropriate spaces on the COCs:

| | |
|---|---|
| **Name (for Reporting):** | Designated AECOM Project Manager |
| **Company:** | AECOM |
| **Address:** | (INSERT Task Manager address) |
| **City, State, Zip Code:** | (INSERT Task Manager address) |
| **Phone:** | (INSERT Task Manager phone) |
| **Fax:** | (INSERT Task Manager fax) |
| **Email:** | njlabdata@aecom.com |
| **Name (for Invoicing):**<br>**Company:** | Erin Farrell<br>AECOM |
| **Address:** | 30 Knightsbridge Road, Suite 520 |
| **City, State, Zip Code:** | Piscataway, NJ 08854 |
| **Phone:** | (732) 564-3609 |
| **Fax:** | (732) 369-0122 |
| **Email:** | Erin.Farrell@aecom.com |
| **Samplers Name:** | This person must be the same person that relinquishes initial custody. |
| **Sample Delivery Group (SDG) No.** | The SDG Number will be recorded when assigned by the laboratory. The PPG Site Number will be included in the Sample ID. |
| **Purchase Order (PO) Number:** | AECOM's PO number (provided to the sampler by the Task Manager) |
| **AECOM Project Number** | **INSERT Task Specific Project Number (Mandatory Information to be Required on all COCs)** |
| **Site/Project Identification:** | PPG Site Number |
| **Case Type:** | NJ –Administrative Consent Order |

Any special instructions are to be filled in on every page of the COCs and page numbers must be written at the top right corner of the COC.

Aqueous and non-aqueous (soil, chip, wipe, sweep, waste, core) samples will be packed in coolers and transported, as needed, from the field to the laboratory by courier, laboratory representative, or AECOM personnel. For air samples, sample cassette /plastic mailer assemblies should be placed in a clean Ziploc® bag and the bag should be packed with small bubble wrap snugly in a clean shipping container or cooler to prevent movement of the samples during shipment. To preserve the samples during transit, blue ice packs will be placed inside the shipping cooler as standard practice. Refer to POP PPG 019. Samples are generally shipped daily to arrive at the laboratory within 24 hours of collection. Sample containers will be placed in a cooler packed with an absorbent material such as vermiculite and packed with ice to maintain a temperature of 4°C.

All sample containers will be labeled as described above. All sample documentation will then be affixed to the underside of each transport container lid. If samples are shipped to the laboratory via overnight air transportation (e.g., Federal Express) or by commercial courier, the COC record identifying the contents will be enclosed in each sample cooler and the cooler will be taped closed with fiberglass tape covering the custody seals. If a laboratory courier is used, the courier will sign the COC before departing the site. The transport container lid will then be closed and affixed with a custody seal. The coolers will be locked or secured with strapping or packing tape and sealed with custody seals. The preferred procedure is to attach a custody seal to the front right and back left of the cooler. The back copy of the COC will be detached and kept as part of the field records. The original record and remaining copies will accompany the coolers.

Regulations for packaging, marking/labeling, and shipping hazardous materials and wastes are issued by the USDOT. Air carriers which transport hazardous materials, such as Federal Express, may also require compliance with the current edition of the International Air Transport Association (IATA) Dangerous Goods Regulations. The IATA protocol details the procedures for the shipment and transportation of hazardous materials by a common air carrier. It is important to note that following all current IATA regulations will ensure compliance with USDOT protocol.

## 10.2 Laboratory Custody Procedures

The laboratory will be responsible for receiving the samples and logging them in. On arrival at the laboratory, all samples will be inspected thoroughly to confirm that the integrity of the samples and containers has not been compromised. The cooler custody seals will be inspected to verify that they are still intact and were properly signed and dated by the field sampling team. The individual sample containers will be inspected to verify that each has a sample label. The condition of the samples may be noted on the COC form under "Remarks".

The sample containers will be checked against the accompanying chain-of-custody to verify that the cooler contents are identical to the samples described on the COC documents. If discrepancies exist, they will be reported to the designated Project Manager by the Laboratory's Project Manager. The problem will be resolved, in writing (e.g., email, fax, memo, etc.), before the samples are logged in.

After it has been determined that the samples are in satisfactory condition and the documents are in order, each sample will be assigned a unique laboratory identification number. A sample log-in sheet will be initiated and will serve as documentation as to the condition of the samples upon receipt and cross-referenced between field identification numbers and assigned laboratory numbers.

After the samples have been entered into the laboratory tracking system, copies of the log-in forms and chain-of-custody records will be sent to the Project Manager, who will verify that the specified samples and parameters correspond to the samples and parameters identified in the FSP/QAPP. The samples will be placed in a secured storage area, under the conditions called for by the analytical method, until taken for analysis. Samples removed from the secure area for preparation or analysis will be tracked using internal custody forms.

Typically, samples will not be delivered on Saturday or Sunday. If Saturday delivery is required, the laboratory will be notified in advance.

# 11.0 Calibration Procedures

This section describes procedures for maintaining the accuracy of all the instruments that are used for conducting field tests and laboratory analyses. These instruments will be calibrated at the frequencies recommended by the manufacturer and the information will be recorded in the appropriate field book.

## 11.1 Field Instrument Calibration

Instruments used to gather, generate, or measure environmental data will be calibrated with sufficient frequency and in such a manner that accuracy and reproducibility of results are consistent with the manufacturer's specifications. Field instruments will be issued through a formal tracking system and operated by trained personnel, in accordance with the appropriate POPs or manufacturer's specifications. Each instrument used in the field will be examined daily by the AECOM FOL or his designee to verify that it is operating properly.

Field instruments will include a PID; hydrogen sulfide portable, hand-held monitor; air monitoring units containing continuous gas chromatographs (GC) fitted with a PID; the MiniVol™ portable (tactical) air sampler; water level meter; multi-parameter water quality meter; turbidity meter; and an aerosol/dust monitor. Calibration procedures will be performed according to the applicable SOP(s) and/or POP(s) in **Appendix B** work plans, and/or applicable manufacturer's instructions. In general, each instrument will be calibrated daily before its initial use. The calibration will be checked periodically according to the manufacturer's recommendations and/or the requirements in the applicable SOP(s), POP(s) and work plans. Calibration and calibration check results will be recorded in calibration log forms or in the field logbook. Preventative maintenance will be performed by the equipment rental agency supplying the instruments.

Calibration procedures will be documented in the field records. Documentation will include the date and time of calibration, the identity of the person performing the calibration, the reference standard used, the readings taken, and any corrective action. This information will be incorporated into the appropriate reports to be submitted to NJDEP for review. In addition to the manufacturer's recommended calibration procedures and frequencies, the contractor's preventive maintenance and internal calibration schedule will be provided and kept at the site for review by the NJDEP auditor. Field instruments will be calibration checked at a minimum of twice daily, before and after use. A calibration curve will be run every six (6) to eight (8) weeks. Documentation will also include the calibration curve, as well as a log of field calibration dates and standards.

### 11.1.1 Laboratory Instrument Calibration

Calibration is required to ensure that the analytical system is operating correctly and functioning at the proper sensitivity to meet the detection limits established for the method (refer to the applicable SOPs in **Appendix D**). These methodologies include specific instrument calibration procedures and frequencies that will be followed by the laboratory. If an instrument has not been properly calibrated and the quality of the data has been adversely affected, the corrective actions outlined in the methodologies will be implemented.

The laboratory maintains documentation for each instrument which includes the following information: instrument identification, serial number, date of calibration, analyst, calibration solutions, and the samples associated with these calibrations.

# 12.0 Laboratory Operations

## 12.1 Analytical Procedures

The analytical methods shown in **Appendix D, Laboratory SOP Lists**, will be used for all site specific analyses, such as, hexavalent chromium and total chromium. Additional analyses may be required including those for volatile and semi-volatile organics, PCBs, and additional metals. The site-specific work plans for each site will provide a specific list of analytes. SW-846 Methods are used for determination of volatile and semivolatile organics, metals, and hexavalent chromium; these methods are consistent with the regulatory requirements of this program but permit flexibility to maximize data usability with regard to sample preparation and clean up, and analytical sensitivity. Contract Laboratory Program (CLP)-type quality control requirements will, however, be implemented for all analyses as noted in **Section 12.3** of this document.

The laboratories identified in **Section 2.2** will be responsible for conducting all chemical analyses specified in **Appendix D**. Sample handling protocols, analytical procedures, and reporting procedures employed by the laboratories are described in the laboratory SOPs (**Appendix D**) and in the Quality Assurance Plan for each laboratory (which can be provided upon request).

## 12.2 Bottle Preparation

The laboratories will provide properly prepared containers for sampling in a convenient insulated shipping container/cooler. COC seals and forms are provided to ensure complete documentation during sample transport, sampling and analysis. The laboratories provide both chemical preservatives and ice packs in the coolers to ensure that proper preservation techniques are performed and preservation requirements are met. The laboratories provide new, properly cleaned sample containers in the cooler for sample collection. The laboratories do not prepare solvent rinsed sample containers. Solvent rinsed bottles are purchased as projects necessitate. The vendor-prepared bottles are prepared by USEPA protocol. The bottle and preservation requirements for the non-residential sites are summarized in **Appendix C**.

Bottle preparation procedures are described in Specifications and Guidance for Contaminant-Free Sample Containers, EPA-540/R-93/051. The selected laboratories provide containers from suppliers who meet or exceed the requirements outlined in this document; each lot of bottles is delivered with documentation certifying that the containers meet USEPA specifications. The laboratory sample management staff documents the receipt of each bottle shipment upon delivery. The bottle size, vendor lot number, date received, date submitted for quality control checking and date approved for use are recorded in a Bottle Receipt Logbook.. The lot certificate of analysis supplied by the bottle manufacturer is archived by the laboratory Quality Assurance Manager; this information is available on request.

## 12.3 Quality Control

Each laboratory has a QC program in place to ensure the reliability and validity of the analysis performed at the laboratories. All analytical procedures are documented in writing as SOPs and each SOP includes a QC section which addresses the minimum QC requirements for the procedure to meet CLP requirements. The internal QC checks differ slightly for each individual procedure but the following general QC requirements are incorporated as appropriate to the analytical procedure:

- Method blanks;
- Reagent/preparation blanks (inorganic parameters);
- Instrument blanks;
- MS/MSDs;
- Surrogate spikes;
- Laboratory duplicates
- Laboratory control sample (LCS);
- Post-digestion spike
- Internal standard areas;
- Mass tuning;
- Inductively Coupled Plasma (ICP) serial dilutions; and
- ICP interference check samples.

## 12.4 Data Reduction and Reporting

Data reduction, QC review, and reporting will be the responsibility of the analytical laboratory and is discussed in this section. Data assessment, including a formal data validation procedure, will be conducted by AECOM. AECOM will also conduct data reduction to facilitate the use of raw data in site evaluations. This process is discussed in the next section.

### 12.4.1 Data Reduction

Data reduction includes all automated and manual processes for reducing or organizing raw data generated by the laboratory. For all published and referenced methods, the laboratories adhere strictly to the requirements of the method for calculation of results. Further details are supplied in the laboratories' Standard Operating Procedures.

### 12.4.2 Data QC Review

Prior to being released as final, laboratory data will proceed through a tiered review process. Data verification starts with the analyst who performs a review of the data to ensure the work was done correctly the first time. Following the completion of the initial verification by the analyst performing the data reduction, a systematic check of the data will be performed by an experienced peer or supervisor. This check will be performed to ensure that initial review has been completed correctly and thoroughly. A third-level review will be performed by the Laboratory Project Manager before

results are submitted to clients. This review serves to verify the completeness of the data report and to ensure that project requirements are met for the analyses performed.

### 12.4.3 Data Reporting

The full analytical, quality control, and deliverables requirements (3 electronic copies, and one paper copy for chromium results; full data packages for all analytes) will be provided with the final Remedial Investigation Report, including New Jersey Electronic Data Deliverable (EDD), to be submitted to NJDEP. At a minimum, the data included in the laboratory report will meet the requirements of the Reduced Laboratory Data Deliverables for non-USEPA CLP Methods. A fully validatable CLP-type data package containing all raw data will be requested for those data sets being subjected to full data validation.

Full laboratory data deliverables, as detailed in Appendix A of the NJDEP *Technical Requirements for Site Remediation* (November 2009) will be submitted for all hexavalent chromium and hexavalent chromium associated (pH, Eh, sulfides, etc.) analyses. The full laboratory data deliverables will consist of the following:

- three electronic copies of the laboratory data package on CD in Adobe portable document format (pdf),
- one paper copy of the laboratory data package,
- three electronic copies of the analytical data using the format NJDEP's 1999 *Electronic Data Interchange Manual*,
- and one electronic copy of the analytical data in the EQuIS four-file format, as modified by AECOM.

Reduced laboratory data deliverables, as detailed in Appendix A of the NJDEP *Technical Requirements for Site Remediation* (November 2009), will be submitted for all other analytical data (ex, metals, VOCs, etc.). The reduced laboratory data deliverables will consist of the following:

- one electronic copy of the laboratory data package on CD in Adobe pdf will be submitted,
- three electronic copies of the analytical data using the format NJDEP's 1999 *Electronic Data Interchange Manual*,
- and one electronic copy of the analytical data in the EQuIS four-file format, as modified by AECOM.

# 13.0 Data Validation

Each data package will undergo a formal review procedure. The validation will be performed by the AECOM data validation staff under direction of the AECOM Data Validation Manager.

## 13.1 Data Validation

Validation of the laboratory deliverables will be performed by AECOM. One hundred percent of the analytical data will be reviewed, either as full or limited validation or for completeness. The percentage of the data for each level of validation will be identified in the site-specific work plan for each program.

For full validation, the data will be reviewed for the following, where applicable to the method:

- Completeness of deliverable;
- Technical holding times and sample preservation;
- Laboratory and field blank contamination;
- Surrogate spike recoveries,
- Field and laboratory duplicates;
- MS/MSD recoveries and RPDs;
- Post-digestion spike recoveries;
- LCS recoveries;
- Initial and continuing calibrations;
- Instrument tuning,
- Internal standard performance,
- ICP serial dilution results;
- ICP interference check sample results; and
- Calculation and transcription verifications (i.e., verifying summary data against raw data).

Limited validation will be based on information presented on summary forms and will include the following:

- Completeness of deliverable;
- Technical holding times and sample preservation;
- Laboratory and field blank contamination;
- Surrogate spike recoveries,

- Field and laboratory duplicates;
- MS/MSD recoveries and RPDs; and
- LCS recoveries.

The discovery of significant anomalies or discrepancies during validation using the summary forms may result in an in-depth review of the raw data and the incorporation of additional review elements into the validation of all data.

AECOM will perform validation of soil and aqueous samples according to the following validation protocols:

- Target Compound List (TCL) Organics, USEPA Region 2 Data Validation Guidance, which will be modified as required to reflect the actual laboratory SOPs used for this program.):
  - *Validating Volatile Organic Compounds by SW-846 Method 8260B, SOP-HW-24*, Rev.2, October 2006;
  - *Validating Semivolatile Organic Compounds by SW-846, Method 8270; SOP HW-22*, Rev 3, October 2006
- Target Analyte List (TAL) Inorganics, NJDEP Office of Data Quality Data Validation (DV) SOP:
  - SOP 5.A.16 , Rev. 1, Quality Assurance Data Validation of *Analytical Deliverables for Inorganics (based on USEPA SW-846 methods);* May 2002.
- Hexavalent Chromium, NJDEP Office of Data Quality DV SOPs:
  - SOP 5.A.9, Rev.1, *Standard Operating Procedure for the Completion of the Hexavalent Chromium Data Validation Report Forms and the Preparation of the Final Data Validation, October 2001.*
  - SOP 5.A.10, Rev.3, *Standard Operating Procedure for Analytical Data Validation of Hexavalent Chromium,* September 2009.

Data for $PM_{10}$ and hexavalent chromium in air will be reviewed for adherence to the respective SOP, and the laboratory precision and accuracy control limits contained in the method.

Once the validation for a data package is completed, a validation report will be prepared. This report will summarize the samples reviewed, elements reviewed, any nonconformances with the established criteria, and validation actions (including application of data qualifiers). Data qualifiers will be consistent with the NJDEP SOPs. Data validation results will be presented in accordance with the NJDEP "hit list" format using the template provided in **Appendix E**. A copy of each validation report as well as the analytical data package will be forwarded to the NJDEP for review with each report submittal.

## 13.2 Data Assessment

Following data validation, the AECOM project technical staff will assess the data for usability. Data assessment activities will examine site-specific factors which interfere with chemical analyses or utility of the results. Some of the factors which will be assessed include:

- Adverse matrix effects on the analytical recoveries.
- Nature and cause of extraneous contamination not attributable to laboratory contamination.
- Reproducibility of results for site-specific media in relation to stated precision goals.
- Adequacy of the data base in terms of numbers of samples, critical data points, and representativeness for meeting stated objectives.

Validated data and related assessments will be reported in appropriate charts and tables in the RI report.

## 13.3 Data Reliability

The overall reliability of the data will be assessed primarily using the results of the data validation process and will include a discussion of the effect of any nonconformances with regard to holding times, sample preservation, blank contamination, instrument calibration, and QC analyses. The usability of hexavalent chromium data will be evaluated based on the pre-digestion and post-digestion spike recoveries and the parameters indicative of oxidizing/reducing conditions.

# 14.0 Performance and System Audits

A system audit is defined as a qualitative evaluation of the components of a measurement system to determine their proper selection and use. A performance audit is a quantitative evaluation of the measurement system that requires testing of the system with samples of known composition or behavior to evaluate precision and accuracy.

## 14.1 Field Procedures

### 14.1.1 Field Performance Audits

It will be the responsibility of the AECOM FOL to continually monitor the performance of the field team, including subcontractors, for conformance to the site-specific work plan(s) and the FSP/QAPP. Any problems or deficiencies will be communicated to the Project Manager and project QAO. A record of any problems encountered, and their resolution, will be maintained in the field notebook.

Field performance will also be evaluated based on the analytical results of the field blanks and field duplicates. Field blanks assess the effectiveness of measures taken in the field to minimize cross contamination. The results of field duplicates reflect the ability of the field team to collect representative sample portions of each matrix type.

### 14.1.2 Field System Audits

Internal audits of field activities will be conducted periodically by the project QAO (or designate) during the field sampling program. Follow-up audits will be conducted if significant problems are encountered.

The audits will cover the execution of sample identification, sample control, COC procedures, field sampling and documentation, agreement with QA/QC objectives, FSP/QAPP and site-specific work plan(s). The audits will involve a review of field logbooks and standard forms, COC records, and instrument calibration records. The project QAO will review field performance with the FOL.

During the field performance audit, the auditor will maintain a record of the audit with written field notes. Preliminary results of the audit will be reviewed with the FOL. Corrective action for deficiencies that adversely affect the quality of the data will be implemented immediately.

Upon completion of the audit, the project QAO will develop an audit report in the form of a memorandum that summarizes the audit findings and identifies those areas still requiring corrective measures. This report will be submitted in memorandum form to the AECOM Project Manager, Task Manager, FOL, to NJDEP as well as to the project file. The resolution of final action as described in **Section 17.0** of the FSP/QAPP will be subsequently implemented.

## 14.2 Laboratory Audits

AECOM has contracted NJDEP-certified laboratories to perform all laboratory analysis of soil and groundwater sampling performed by AECOM.

### 14.2.1 Laboratory Performance Audits

Continuous performance auditing is accomplished through the regular use of LCS, matrix spike samples, duplicate samples, QC samples, proficiency testing, and through continuing calibration verification samples. Federal and State agencies may administer the proficiency testing.

### 14.2.2 Laboratory System Audits

The laboratory will conduct regular audits of facilities, processes, and procedures according to written protocols established by the laboratory QA Program. These audits will be conducted by the laboratory's QA Officer and the results documented in the laboratory analytical reports.

Laboratory audits are conducted periodically by AECOM or another qualified party as part of their analytical subcontractor monitoring program. The laboratory audit includes a review of the following areas:

- QA organization and procedures;
- Personnel training and qualifications;
- Sample log-in procedures;
- Sample storage facilities;
- Analyst technique;
- Adherence to laboratory SOPs;
- Compliance with QA/QC objectives;
- Instrument calibration and maintenance;
- Facility security;
- Bottleware preparation;
- Waste management;
- Data archival;
- Data recording, reduction, review, and reporting; and
- Cleanliness and housekeeping.

Preliminary results of the systems audit are discussed with laboratory personnel in an on-site debriefing. A written report that summarizes audit findings and recommends corrective actions is prepared and submitted to the laboratory for response, to the AECOM Project Manager and will be submitted to NJDEP as well. The results of the audit, including resolution of any deficiencies, are included in the QA reports to management as described in **Section 17**.

# 15.0 Preventative Maintenance

## 15.1 Field Instruments

Field instruments will be rented through an equipment rental company. Preventive maintenance for all field instruments is conducted according to applicable manufacturer's instructions by the rental company. A representative log for maintenance or calibration of field instruments is included with the rental unit. Instrument instruction manuals will be maintained with the rental unit.

AECOM field personnel will be responsible for ensuring that the instruments are properly functioning. At a minimum, this will entail checking the instrument prior to shipment to the field and performing daily operational checks and calibration as described in **Section 11**. Routine maintenance and trouble-shooting procedures will be performed as described in the manufacturer's instructions. All calibration and maintenance procedures will be documented in field records. Spare parts will be readily available on site or from the vendor. Preventive maintenance for all field instruments will be conducted according to applicable manufacturer's instructions, NJDEP guidance, and rental company SOPs.

Instrument instruction manuals will be available on site. Critical spare parts such as lamps, probes, and battery chargers will be kept on site to minimize downtime.

## 15.2 Laboratory Instruments

The laboratories will conduct preventative maintenance routinely on each analytical instrument and analytical instruments will be maintained and serviced in accordance with the manufacturer's specifications, laboratory SOPs, and analytical methods.

# 16.0 Corrective Action

Corrective action is the process of identifying, recommending, approving, and implementing measures to counter unacceptable procedures or out-of-limit QC performance that can affect data quality. Corrective action can occur during data compilation, data import, data validation, and data assessment. Any nonconformance with the established QC procedures in the FSP/QAPP will be identified and corrected in accordance with the FSP/QAPP. Corrective actions proposed and implemented in response to potential data quality issues will be documented in the QA sections of project deliverables. The following procedures should be followed when problems are identified and corrective actions are taken:

The person who identifies the problem is responsible for notifying the AECOM Project Manager, relevant Task Manager, and project QAO.

- Corrective action should only be implemented after approval by the AECOM Project Manager, or his designee (generally the FOL).
- If immediate corrective action is required, approvals may be secured by telephone from the AECOM Project Manager.
- All corrective actions should be documented in writing.

Corrective actions are defined as those measures taken to rectify a laboratory or field measurement system that exceeds its control limits. These actions may be initiated by any person performing work in support of investigation or remediation activity. The need for corrective action may be identified by system or performance audits or by standard QC checks. The essential steps in the corrective action process are:

- Identifying and defining the problem;
- Assigning responsibility for investigating the problem;
- Investigating and determining the cause of the problem;
- Determining a corrective action to eliminate the problem;
- Assigning and accepting responsibility for implementing the corrective action;
- Implementing the corrective action and evaluating its effectiveness; and
- Verifying that the corrective action has eliminated the problem.

## 16.1 Sample Collection/Field Measurements

Corrective action in the field can be needed when:

- The sample network is changed (i.e., more or fewer samples, sampling locations other than those specified in the site-specific work plan(s) and/or FSP/QAPP, etc.);

- Sampling procedures and/or field analytical procedures require modification because of unexpected conditions; or
- The integrity of field measurements or samples is in question.

The field team members will be responsible for identifying any suspected technical or QA deficiencies and reporting them to the AECOM FOL. The AECOM FOL will be responsible for assessing the suspected deficiency, for determining the impact on the quality of the data (in consultation with the project QAO, Task Manager, and Project Manager), developing the appropriate corrective action, and ensuring it is implemented. If the corrective action augments the original scope of the sampling plan (i.e., increases the numbers or types of samples/analyses) and uses existing and approved procedures in this FSP/QAPP, approval by the AECOM FOL and AECOM Project Manager will be sufficient. If the corrective action results in a reduced scope of the work, significant alterations in sample location, major modifications to analytical methods, or causes the project data quality objectives not to be achieved, it will be necessary for all levels of project management to concur with the proposed action.

If problems with field measurements occur, corrective action may include:

- Repeating the measurement to check the error;
- Checking for all proper adjustments for ambient conditions such as temperature;
- Checking the batteries;
- Recalibrating equipment;
- Checking the calibration;
- Replacing the instrument or piece of equipment; or
- Stopping work.

If, during his/her review of sampling operations, the AECOM FOL determines that the integrity or quality of the sample(s) has been adversely affected, the following corrective measures may be implemented:

- Reviewing sampling and/or COC procedures and modifying as necessary;
- Replacing or repairing sampling equipment;
- Collecting replacement sample(s); or
- Stopping work.

Deficiencies may also be noted during internal field audits. The project QAO will identify the deficiencies and recommend the appropriate corrective action to the AECOM Project Manager. Upon approval by the AECOM Project Manager, the AECOM FOL, Task Manager, and field team members will be responsible for implementing the corrective action. If the use of unapproved methods, or the improper use of approved methods, is adversely affecting the data, corrective action may be implemented immediately.

Corrective actions will be documented in the field records. Documentation will include:

- A description of the circumstance that initiated the corrective action;
- The action taken in response;
- The final resolution; and
- Any necessary approvals.

Corrective action resulting from internal field audits will be documented in the QA reports to management per **Section 17**. No staff member will initiate corrective action without prior communication of findings through the proper channels.

## 16.2 Laboratory Analyses

Laboratory personnel will be alerted that corrective actions may be necessary if:

- QC data are outside the warning or acceptable windows for precision and accuracy;
- Blanks contain target analytes above acceptable levels;
- Undesirable trends are detected in spike recoveries or RPD between duplicates;
- There are unusual changes in detection limits;
- Deficiencies are detected by the QA department during internal or external auditors or from the results of performance evaluation samples; or
- Inquiries concerning data quality are received.

Corrective action procedures may be handled at the bench level by the analyst, who will review the preparation or extraction procedure for possible errors, check the instrument calibration, spike and calibration mixes, instrument sensitivity, and so on. Corrective action will be in accordance with method protocol (when applicable). If the problem persists or cannot be identified, the matter will be referred to the laboratory supervisor, manager and/or QA department for further investigation. If the nonconformance causes the project objectives not be achieved, the AECOM Project QAO will be notified, who in turn will communicate the issue to the AECOM Project Manager and Task Manager.

Corrective actions will be performed prior to the release of data from the laboratory. The corrective action will be documented in both the laboratory's corrective action files, and in the narrative data report generated by the laboratory.

## 16.3 Data Validation/Data Assessment

The need for corrective action may be identified during either data validation or data assessment. Potential types of corrective action may include re-sampling by the field team or re-injection and reanalysis of samples by the laboratory. These actions are dependent upon the ability to mobilize the field team, whether the data to be collected are necessary to meet the required QA objectives, and physical limitations on the ability to recollect or reanalyze the sample.

The need for corrective action may be identified by the data validator or by a member of the project team assessing the data. The person responsible for identifying the corrective action situation will notify the AECOM Project Manager, who will be responsible for approving implementation of the corrective action. All corrective actions of this type will be documented by the project QAO in the QA reports (**Section 17**).

# 17.0 Quality Assurance Reports

As part of the requirements of each member of the project team, notification will be submitted to the project QAO to ensure that any problems identified during the sampling and analysis programs are investigated and the proper corrective measures taken in response. The FOL and Task Managers will assist the project QAO in preparing the QA reports. These reports will be prepared on an as-needed basis and will include:

- Summary of the status of field activities, including compiled field data sets and the results of field audits;
- Periodic assessment of measurement data accuracy, precision, and completeness;
- Data validation results;
- Summary of the status of laboratory activities, including timely submittal of analytical results, and compilation of QC data; and
- Any other QA issues relevant to the project, including corrective action situations, resolutions of previously stated problems, summaries of training programs, results of any performance evaluation audits, and any minor changes to this FSP/QAPP.

These QA reports will be prepared in writing by the project QAO who will provide compilation report(s), as necessary to the AECOM Principal-in-Charge, Project Manager, and to NJDEP. If serious QA deficiencies are noted, supplemental reports may be submitted.

**NOTES**

CAS No. - Chemical Abstracts System Registration Number
MDL – Method Detection Limit
Mg/kg – milligram per killigram
NA – Not available for this constituent.
NJDEP – New Jersey Department of Environmental Protection
PQL - Practical Quantitation Level as defined in N.J.A.C. 7:9C-1.4
RL – Reporting Limit
TAL – Target Analyte List
TCL – Target Compound List

[1] – The individual RIWPs will indicate the parameters/analytes that will be analyzed.

[2] – Or Allergic Contact Dermatitis (ACD) whichever is lower. ACD for hexavalent chromium is a site-specific determination.

[3] – This analysis may be required if the MS/MSD does not meet QC requirements for hexavalent chromium analysis. The analysis is used to assist in the evaluation of the tendency of Cr+6 to exist or not exist in the unspiked sample. This analysis is only necessary if the unspiked sample contains detectable Cr 6+. .

[4] – TCLP and/or SPLP may be needed for waste characterization

[5] – Test America does not perform this analysis, thus the analysis will be performed by Accutest or GeoTesting Express.

[6] – Test America is pending approval of their NJDEP EPH method; however, Accutest will be the only laboratory used for this analysis until Test America receives NJDEP certification.

[7] – Eh and pH are required to be determined under the hexavalent chromium analysis.

[8] – The laboratory reporting limit(s) (RLs) exceed the NJDEP Soil PQLs; however, since the laboratory RLs are less than both the NJDEP residential direct contact soil remediation standard and NJDEP non-residential direct contact soil remediation standard, these RLs are acceptable for these analytes.

[9] – Health based criterion defaults to background according to Table 1 in the NJDEP Guidance Document *Development of Site-Specific Impact to Ground Water Soil Remediation Standards Using the Soil-Water Partition Equation,* December 2008.

[10] – Standard set a Practical Quantitation Limit (PQL) according to Table 1 in the NJDEP Guidance Document *Development of Site-Specific Impact to Ground Water Soil Remediation Standards Using the Soil-Water Partition Equation,* December 2008.

[11] – Health based criterion defaults to soil saturation limit according to Table 1 in the NJDEP Guidance Document *Development of Site-Specific Impact to Ground Water Soil Remediation Standards Using the Soil-Water Partition Equation,* December 2008.

[12] – The laboratory reporting limit(s) (RLs) exceed one of the NJDEP standards (i.e., Impact to GW, NJDEP Soil PQL, NJDEP residential direct contact soil remediation standard, and/or NJDEP non-residential direct contact soil remediation standard. However, the laboratory MDL in parenthesis is below the NJDEP standards and thus is acceptable. Note, that a laboratory fortified blank (LFB) at a concentration equivalent to the lowest applicable NJDEP standard for those analytes with standards between the RL and MDL will be performed to ensure that the instrument accuracy is acceptable.

[13] - Standard represents a maximum value

[14] – Method has been removed from ASTM, but will only be used for informational purposes during the Feasibility Pilot Studies.

[15] – These parameters do not have applicable NJ certified methods for soil/solid samples. However, the aqueous methods are NJ certified. These parameters in soil are for informational purposes only to support the hexavalent chromium analysis (SW846 3060/7196) if the MS/MSD fails.

[16] – These parameters do not have applicable NJ certified methods for soil/solid samples. However, the aqueous methods are NJ certified. These parameters in soil are for informational purposes only to support the feasibility pilot studies to monitor the treatment.

[17] – Impact to GW soil remediation standards must be developed on a site-specific basis for chromium. For Class II GW, the GW quality standard is 70 ug/l (measured as total chromium), but assuming it is all in the form of hexavalent chromium. In addition to the cleanup criteria listed above, all remedial actions at sites that have hexavalent chromium must comply with Commissioner Jackson's memorandum dated February 8, 2007. A copy of this memorandum can be found on the Department web site at http://www.state.nj.us/dep/dsr/chromium/crmorlift200702.pdf

**Notes:**

[1] – The individual RIWPs will indicate the parameters/analytes that will be analyzed.

[2] - Cr+6 Reanalysis may require these additional parameters if the matrix spike/matrix spike duplicate do not meet QC requirements.

[3] - GW criteria is for total chromium

[4] - GW criteria is for vanadium pentoxide

[5] - GW criteria is for total xylenes

[6] - GW criteria is for Oil & Grease & Petroleum Hydrocarbons

[7] - The laboratory RLs exceed the NJDEP PQLs; however, the laboratory RLs are less than the NJDEP Specific GW Quality Criteria and thus are acceptable.

[8] – Test America does not perform this analysis, thus the analysis will be performed by Accutest.

**Acronyms:**

CAS - Chemical Abstracts System Registration Number
NA - not available for this constituent
NJDEP New Jersery Department of Environmental Protection
PCB - Polychlorinated Biphenyl
PQL - Practical Quantitation Level as defined in N.J.A.C. 7:9C-1.4
RL - Reporting Limit
SVOC- Semivolatile Organic Compound
TAL - Target Analyte List
TCL - Target Compound List
µg/L – microgram per liter
VOC - Volatile Organic Compound

## TABLE 6-1 QUALITY CONTROL SAMPLE SUMMARY

Project Operating Procedure

# Recording of Field Data

## 1.0 Scope and Applicability

**1.1** Purpose and Applicability

This Project Operating Procedure (POP) provides instructions for recording data when documenting a sample collection event, field measurements, or a site visit. Field data may be recorded in field logbooks, on standardized forms, as annotated maps, as photo documentation, or electronically. Chain-of-custody records are also considered field data; however, these records are specifically addressed in POP PPG 002 Chain of Custody Procedures and POP PPG 003 Packaging and Shipment of Environmental Samples.

## 2.0 Health and safety considerations

**2.1** Not Applicable

## 3.0 Interferences

**3.1** Not Applicable

## 4.0 Equipment and materials

The following materials are necessary for this procedure:

- Bound field logbook (preferably waterproof, such as Rite-in-Rain™)
- Standardized field data sheets (refer to individual POPs for test pit logs, boring logs, groundwater sample collection logs, etc.)
- Pen or SharpieTM
- Watch or other time-keeping device

The following materials may also be needed:

- Site maps
- Clipboard
- Three-ring binder or equivalent
- Camera
- Hand-held electronic recording device (e.g., PDA, laptop, or tablet PC)

## 5.0 Procedures

### 5.1 General

Field activities vary widely and no general rules can specify the exact information that must be recorded for each event. However, the field records must contain sufficient detail so that persons going to the site could reconstruct a particular situation without reliance on the collector's memory.

Field logbooks may be supplemented by standardized forms (e.g., well construction and development, sample collection forms, drum logs). In that case, the logbook provides a chronology of events, summary of personnel on site, and a narration of events not covered by the standardized forms. It is recommended that the details recorded on the standardized forms not be replicated in the logbook due to the potential for transcription errors and inconsistencies. References to standardized forms must be included in the logbook.

Entries will be recorded legibly in permanent ink (a black ballpoint pen is preferable) and will be signed and dated. No erasures or obliterations will be made. If an incorrect entry is made, the information will be crossed out with a single strike mark which is initialed and dated by the sampler, and the correct information added.

Pencils should not be used. If a ballpoint pen cannot be used because of adverse weather conditions (rain or freezing temperatures), a fine-point Sharpie™ is an acceptable substitute. If conditions are such that only pencil can be used, an explanation must be included in the logbook and the affected data should be photocopied, signed as verified copy, and maintained in the project files as documentation that the data has not been changed.

Information to be recorded should address the questions of who, where, what, when, how, and why. A specific list of information that should be recorded is included in Table 1.

Entries will be objective, factual, and free of personal feelings or inappropriate language. Cryptic notes and undefined abbreviations or acronyms should be avoided.

Information will be made in as close to real time as possible. Information recorded significantly after the fact must be dated as such.

### 5.2 Field Logbooks

Field logbooks will be bound water-proof field survey books or notebooks with consecutively numbered pages.

Logbooks will be assigned to field personnel, and will be identified by a unique document number. The logbook should be kept in the field person's possession or in a secure location during field activities and archived in the project files upon completion of the field program.

Logbooks should be specific to a project. Multiple projects should not be included in one logbook because of document retention and evidentiary reasons.

The title page of each logbook will contain the following:

- Person to whom the logbook is assigned, AECOM office location, and phone number,
- The logbook number,
- Project name and number, and
- Start and end dates of work covered by the logbook.

Logbook entries documenting sample collection or field measurements must clearly identify the task being completed (for example, water level measurements, headspace readings). Units must be included for all measurements.

For ease of reference, it is recommended that a new page be started for each sampling day and that the time be recorded in the far left column. Each day's entries will be signed and dated by the person making the entries. A diagonal line across the bottom of the page will indicate the end of an entry.

**5.3** Standardized Forms

- At a minimum, each form must include a title identifying the activity being documented and the project identification (name and number).
- Each form must be signed and dated by the person completing the form.
- There should be no blank spaces on the form. Each space must be filled in with the information requested or "NA" (not applicable).
- Forms should not be loose, but should be maintained in an organized manner (e.g., clipboards, binders).

**5.4** Maps and Drawings

Maps and drawings that document final sampling locations and which are separate from the field logbook must be referenced in the logbook. These maps or drawings must include the project name and number, site identification and location, and must be signed and dated by the person recording the locations.

Maps and drawings must include compass orientation and scale.

**5.5** Photographs and Other Photo Documentation

Photo documentation, if permitted at the site, can provide invaluable information on site conditions, sample locations, and the sample itself.

Photographs, videos, or slides must be cross-referenced to entries in the field logbook or on a photo documentation log. Information to be recorded includes name of photographer, date, time, direction faced, description of subject, and sequential number of the photograph and roll number. An indication of scale is also helpful. Image-enhancing techniques (lenses, film) should also be noted.

**5.6** Electronic Files

Electronically captured data may include data logging systems and hand-held electronic recording devices such as PDAs, laptops, or tablet PCs.

Field data that is captured electronically must be cross-referenced in the field logbook. Information to be recorded includes the identity of the person recording the data, instrument make and model number, measurement time and date, and file identification.

Sufficient backup systems must be in place to protect against the loss of data. Electronic files must be saved to a disk or backed up immediately upon completion. The backup disk or other media (CD, flash drive) should then be stored in a secure location separate from the laptop, tablet, or PDA.

Files must be uniquely identified and should be stored in the project files on the network. An unedited version of the file must be maintained and all subsequent manipulations tracked.

## 6.0 Quality assurance / quality control

Field records provide evidence and support for technical decisions, interpretations, and judgments. It is therefore critical that procedures and systems be in place to ensure that they are legible, identifiable, and retrievable, and protected from loss or damage. In addition, client or regulatory requirements, or the end use of the data (e.g., to support litigation) may determine the format in which the data must be recorded. For example, some projects may require that all field information be recorded in the field logbook and may not allow the use of standardized forms. The requirements necessary to meet the data quality objectives for a particular project will be defined in the site-specific workplan and/or Sampling and Analysis Plan (SAP) hereafter referred to as the project plan.

The field records will be reviewed by the Field Team Leader, or by the Project Manager or his/her designate, for accuracy, completeness, and adherence to the requirements of this POP. At a minimum, this must occur at the end of the field event. For field activities of extended duration, it is recommended that this review occur more frequently (e.g., daily or weekly).

If information recorded in the field is transcribed to another format, the original record must be retained for comparison purposes.

Periodic copying of the field records should be considered to insure against the loss or destruction of the original documents.

## 7.0 Data and records management

At the end of the field program, original field records must be placed in the project files and maintained for a certain retention time. The duration of record retention will be determined by project-specific requirements, or, in the absence of project requirements, by AECOM Corporate policy.

## 8.0 Personnel qualifications and training

The Project Manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources, and guidance necessary to perform the measurements in accordance with this POP and the project plan. In the absence of a Field Team Leader, the Project Manager is responsible for ensuring that field records are reviewed and approved as described below.

The Field Team Leader is responsible for reviewing and approving the field records for accuracy, completeness, and conformance to the procedures in this POP.

Field personnel are responsible for recording data according to the procedures outlined in this POP.

Project Operating Procedure

# Chain-of-Custody Procedures

## 1.0 Project Scope and applicability

Chain-of-custody (COC) is defined as the unbroken trail of accountability that ensures the physical security of samples, data, and records (EPA Glossary of Quality-Related Terms). This project operating procedure (POP) describes COC procedures applicable to environmental samples collected by AECOM during field sampling and analysis programs. Custody procedures within the laboratories analyzing the samples are not addressed.

Samples are physical evidence. The objective of COC procedures is to provide sufficient evidence of sample integrity to satisfy data defensibility requirements in legal or regulatory situations.

The National Enforcement Investigations Center (NEIC) of the U.S. Environmental Protection Agency (EPA) defines custody of evidence in the following manner:

- It is in your actual possession;
- it is in your view, after being in your physical possession;
- it was in your possession and then you locked or sealed it up to prevent tampering; or
- it is in a secure area.

This POP is to be utilized to conduct the work identified in the title of this POP. In the event the Project Manager or Project Team determines that the protocols and procedures listed in this POP are not applicable to the project, the POP will be updated as a subsequent revision.

## 2.0 Health and safety considerations

The health and safety considerations for the work associated with this POP, including both potential physical and chemical hazards, will be addressed in the site-specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

The following may impact the legal or regulatory defensibility of the data:

- The samples are not accompanied by a COC form, and
- The information recorded on the COC form is incomplete, inaccurate, or differs from the information recorded on the sample containers.

## 4.0 Equipment and materials

The following materials are relevant to this procedure:

- COC Form (Figure 1)
- Sample labels
- COC tape or seal (Figure 2)
- Indelible pen or Sharpie™
- Clear plastic sealing tape

Materials identified in related POPs may also be needed.

## 5.0 Procedures

**5.1** Pre-sample collection activities

Some measurement methods require preparation of sample collection media or special treatment of sample containers prior to sample collection. In these cases, COC procedures should be initiated with the media preparation or container treatment. This requires that sample identification numbers or media/container identification numbers be assigned. These numbers should be entered on the COC form, leaving room for the subsequent recording of the associated sample numbers. In this variation, the custodian responsible for media preparation or container treatment has the responsibilities outlined in Section 5.2, and the sampler or field sample custodian has the responsibilities stated in Section 5.3 when he or she receives the prepared media or treated containers. There are a number of acceptable approaches to this variation, and the detailed procedures should be defined in the project-specific Quality Assurance Project Plan (QAPP).

**5.2** Sample collection phase

**5.2.1** As few people as possible should handle the samples. For certain programs, it is helpful if a single person is designated as the sample custodian (the person responsible for the care and custody of the samples until they are transferred to the laboratory for analysis).

**5.2.2** While in the field, sampling personnel should be able to testify that tampering of the samples could not occur without their knowledge. Examples of actions taken may include sealing the sample containers with COC tape or locking the samples in a secure area.

**5.2.3** If samples are to be shipped by commercial overnight carrier, the field sampler or sample custodian completes a COC form (Figure 1) for each cooler/package of samples and places the original of completed form inside the associated cooler/package before the package is sealed (a copy is retained and kept in the field record files). Each completed COC form should accurately list the sample

identification numbers of the samples with which it is packaged, and should contain the identification number of the COC tape on the cooler/package. Representatives of commercial carriers are not required to sign the COC form. Refer to PPG POP 003 Packaging and Shipment of Environmental Samples for specific packaging procedures.

**5.2.4** If samples are hand carried to a laboratory, the person hand carrying the samples is the sample custodian. If the carrier is a different person than the one who filled out the COC form and packaged the samples, then that person transfers custody to the carrier by signing and dating each form in the "Relinquished By" section. The carrier then signs and dates each form in the adjacent "Received By" section. When the carrier transfers the samples to the laboratory, he or she signs and dates each form in the next "Relinquished By" section, and the laboratory sample custodian signs and dates each form in the adjacent "Received By" section.

**5.2.5** If samples are transmitted to the laboratory by courier, the procedures described in either Section 5.2.3 or 5.2.4 are followed, depending on whether the courier is a commercial courier or laboratory representative, and whether the cooler has been secured by COC seals prior to pick up by a laboratory courier.

**5.3** Sample labeling

Labeling of samples occurs at the time of sample collection.

Waterproof, adhesive labels are preferred. Labels should be applied to the container, not the lid whenever possible. Additional interior labels may be required for certain biological samples.

Sample tags may be required for certain projects requiring a strict level of legal or regulatory data defensibility. If tags are utilized, their use will be addressed in the project-specific work plan or QAPP.

Labels should be completed in waterproof, indelible ink. Covering the label with clear plastic tape is recommended to protect the legibility of the label and to prevent the label from detaching from the sample container.

The following information should be recorded on the sample label:

- Project identification (project name and number/client/site)
- Field sample identification code (exactly as it appears on the COC form)
- Sampler's initials
- Date and time of sample collection
- Analyses requested
- Preservation

**5.4** Documentation of sample history

Sample history includes, but is not limited to, preparation of sample containers or collection media (for example, wipes), collection, handling (such as subsampling or compositing), storage, shipment, analytical preparation and analysis, reporting, and disposal.

Refer to PPG POP 001 Recording of Field Data, for specific guidance on documentation of field activities, field measurements, and sample collection.

**5.5** Documentation of custody

It is recommended that a COC form (Figure 1 or equivalent) be initiated upon sample collection. If this is not feasible for a particular project, the COC form may be initiated at the time of sample packaging. If this is the case, the sample collection records will serve as the initial custody document and will document the collection of the sample (sample location and identification, date and time of collection, sampler, and parameters to be analyzed, including containers and preservatives).

The following information is recorded on the COC form:

- Project identification (AECOM project number, client, site name and location).
- Page number (for example, 1 of 2, 2 of 2).
- Field sample identification code. This code should be unique to the sampling event and to the program. This code should agree exactly with the field sample identification code recorded on the bottle label.
- Sampling point location (optional if recorded elsewhere in field records).
- Date and time of sample collection.
- Sample matrix (soil, water, air, etc.).
- Preservative.
- Analysis requested.
- Number of containers.
- Type of sample (grab or composite). Identifying if aqueous samples have been filtered in the field is recommended.
- Signature(s) of sampling personnel and signatures of all personnel handling, receiving, and relinquishing the samples.
- Date(s) and time(s) of each sample transfer.
- Sampler remarks. These comments may serve to alert the laboratory to highly contaminated samples or identify quality control (QC) sample requirements.
- Airbill number (if shipped by overnight commercial carrier).
- Laboratory name and address.

**5.6** COC tape numbers.

The COC is filled out completely and legibly in indelible ink. There should be no unexplained blank spaces. Blank lines should be lined out and initialed and dated.

Data will not be obliterated. Corrections are made, if necessary, by drawing a single line through and initialing and dating the error. The correct information is then recorded with indelible ink.

Information on the COC should agree exactly with that recorded on the sample containers. Discrepancies may result in the samples being incorrectly logged into the laboratory or delays in initiating sample analysis.

**5.7** Sample receipt and inspection

Upon sample receipt, the coolers or packages are inspected for general condition and the condition of the COC tape. The coolers or boxes are then opened and each sample is inspected for damage.

Sample containers are removed from packing material and sample label information is verified against the COC form.

The condition upon receipt, including any discrepancies or problems, is documented and the COC form is completed by signing and recording the date and time of receipt.

Receipt and inspection of samples by subcontractor analytical laboratories will adhere to written procedures established by the laboratory.

## 6.0 Quality assurance / quality control

The records generated in this procedure are subject to review by the sampling team leader, project manager, or designee.

The records generated in this procedure will become a part of the evidence reviewed in the data validation process.

## 7.0 Data and records management

The records generated in this procedure are part of the permanent record supporting the associated measurements and may include, as applicable, the COC forms, sample tags, carrier waybills, and field and laboratory records of sample history (collection, handling, storage, analysis, etc.).

Unanticipated changes to the procedures or materials described in this POP (deviations) should be appropriately documented in the project records.

Records associated with the activities described in this POP should be maintained according to the document management policy for the project.

## 8.0 Personnel qualifications and training

**8.1** Qualifications and training

The individual executing these procedures should have read, and be familiar with, the requirements of this POP.

No specialized skills are necessary in order to implement these procedures; however, an understanding of the concept of custody is useful.

**8.2** Responsibilities

The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

For certain sampling programs, the project manager, sampling team leader, or designee may assign an individual to serve as sample custodian. This individual is responsible for supervising the implementation of COC procedures in accordance with this POP and any project-specific work plans or QAPP.

Figure 2 Example Chain-of-Custody Tape

Project Operating Procedure

# Packaging and Shipment of Environmental Samples

## 1.0 Project Scope and applicability

### 1.1 Purpose and Applicability

This Project Operating Procedure (POP) describes the procedures associated with the packaging and shipment of environmental samples. Two general categories of samples exist: environmental samples consisting of water and soil submitted for routine environmental testing, and waste material samples which include non-hazardous solid wastes and/or hazardous wastes as defined by 40 CFR Part 261 submitted for environmental testing or bench/pilot-scale treatability testing. Packaging and shipping procedures will differ for the two sample categories.

This POP is applicable to packaging and shipment of environmental samples submitted for routine environmental testing. Environmental samples are not considered a hazardous waste by definition; therefore, more stringent Department of Transportation (DOT) regulations regarding sample transportation do not apply. Environmental samples do, however, require fairly stringent packaging and shipping measures to ensure sample integrity as well as safety for those individuals handling and transporting the samples.

This POP is designed to provide a high degree of certainty that environmental samples will arrive at their destination intact. This POP assumes that samples will often require shipping overnight by a commercial carrier service, therefore, the procedures are more stringent than may be necessary if a laboratory courier is used or if samples are transported directly to their destination by a sampling team member. Should the latter occur, the procedures may be modified to reflect a lesser degree of packaging requirements.

Respective state or federal agency (regional offices) protocols may require or recommend specific types of equipment for use in sample packaging or a specific method of shipment that may vary from the indicated procedures. Deviations from this POP to accommodate other regulatory requirements should be reviewed in advance of the field program, should be explained in the project work plan, and must be documented in the field project notebook when they occur.

### 1.2 General Principles

Sample packaging and shipment generally involves the placement of individual sample containers into a cooler or other similar shipping container and placement of packing materials and coolant in such a manner as to isolate the samples, maintain the required temperature, and to limit the potential for damage to sample containers when the cooler is transported.

## 2.0 Health and safety considerations

Sampling personnel should be aware that packaging and shipment of samples involves potential physical hazards primarily associated with handling of occasional broken sample containers and lifting of heavy objects. Adequate health and safety measures must be taken to protect sampling personnel from these potential hazards. The project Health and Safety Plan (HASP) generally addresses

physical and other potential hazards. This plan must be approved by the project Health and Safety Officer before work commences, must be distributed to all personnel performing sampling, and must be adhered to as field activities are performed. In the absence of a HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

Not Applicable

## 4.0 Equipment and materials

- Sample coolers
- Sample containers
- Shipping labels
- Chain-of-custody records, custody seals
- Bubble wrap
- Vermiculite (granular), or styrofoam pellets
- "Blue Ice" refreezable ice packs, or ice cubes
- Transparent tape, or rubber bands
- Fiber tape
- Duct tape
- Zipper-lock plastic bags
- Trash bags
- Health and Safety supplies
- Equipment decontamination materials
- Field project notebook/pen

## 5.0 Procedures

**5.1** General Information

**5.1.1** Regulatory Information

The extent and nature of sample containerization will be governed by the type of sample, and the most reasonable projection of the sample's hazardous nature and constituents. The EPA regulations (40 CFR Section 261.4(d)) specify that samples of solid waste, water, soil or air, collected for the sole purpose of testing, are exempt from regulation under the Resource Conservation and Recovery Act (RCRA) when any of the following conditions are applicable:

- Samples are being transported to a laboratory for analysis;
- Samples are being transported to the collector from the laboratory after analysis;
- Samples are being stored (1) by the collector prior to shipment for analyses, (2) by the analytical laboratory prior to analyses, (3) by the analytical laboratory after testing but prior to return of sample to the collector or pending the conclusion of a court case.

**5.1.2** Sample Information:

The following information must accompany each shipment of samples on a chain-of-custody form (Figure 1) where each sample has an individual entry:

- Sample collector's name, mailing address and telephone number,
- Analytical laboratory's name, mailing address and telephone number,
- A unique identification of each sample,
- Sample description (matrix),
- Number and type of sample containers,
- Container size,
- Preservative,
- Type and method of analysis requested, and
- Date and time that the samples were collected and prepared for shipping,
- Special handling instructions, including notation of suspected high concentration samples.

**5.1.3** Laboratory Notifications:

Prior to sample collection, the Project Manager, or designated alternative must notify the laboratory manager of the number, type and approximate collection and shipment dates for the samples. If the number, type or date of sample shipment changes due to program changes which may occur in the

field, the Project Manager or alternate must notify the laboratory of the changes. Additional notification from the field is often necessary when shipments are scheduled for weekend delivery.

**5.2** General Site Preparation

**5.2.1** Small Projects

Small projects of one or two days duration may require packaging and shipment of samples using the field vehicle as the sample preparation area. If sample coolers will be sent via third party commercial carrier service, adequate sample packaging materials should be sent to the project location in advance of sampling or purchased from stores located near the site.

**5.2.2** Large Projects

Multi-day or week sampling programs usually require rental of an office trailer or use of existing office/storage facilities for storage of equipment as well as for sample preparation. If possible, a designated area should be selected for storage of unused sample containers/coolers and another area for sample handling, packaging, and shipment. Handling of environmental samples should preferably be conducted in a clean area and away from unused sample containers to minimize the potential for cross contamination. Large quantities of packaging materials may require advance special ordering. Shipping forms/labels may be preprinted to facilitate shipping.

**5.2.3** Cooler Inspection and Decontamination

Laboratories will often re-use coolers. Every cooler received at a project location should be inspected for condition and cleanliness. Any coolers that have cracked interior or exterior linings/panels or hinges should be discarded as their insulating properties are now compromised. Any coolers missing one or both handles should also be discarded if replacement handles (i.e., knotted rope handles) can not be fashioned in the field. Replacement coolers may be purchased in the field if necessary.

The interior and exterior of each cooler should be inspected for cleanliness before using it. Excess strapping tape and old shipping labels should be removed. If the cooler interior exhibits visible contamination or odors it should be decontaminated in accordance with POP PPG 014 Decontamination of Field Equipment prior to use. Drain plugs should be sealed on the inside with duct tape.

**5.2.4** Other Considerations

VOC Samples - Sample containers used for VOC analysis may be grouped into a single cooler, with separate chain-of-custody record, to limit the number of trip blanks required for transportation and analysis. Individual VOC samples may also be placed into Zipper-lock bags to further protect the samples.

Contaminated Samples - Sample containers with presumed high contaminant concentrations should be isolated within their own cooler with each sample container placed into a Zipper-lock bag.

**5.3** Sample Packaging Method

Sample packaging should be conducted in the following manner:

Place plastic bubble wrap matting over the base of each cooler or shipping container as needed. A 2- to 3-inch thickness layer of vermiculite may be used as a substitute base material.

Insert a clean trash bag into the cooler to serve as a liner.

Check that each sample container is sealed, labeled legibly, and is externally clean. Re-label and/or wipe bottles clean if necessary. Clear tape should be placed over the labels to protect them. Wrap each sample bottle individually with bubble wrap secured with tape or rubber bands. Place bottles into the cooler in an upright single layer with approximately one inch of space between each bottle. Do not stack bottles or place them in the cooler lying on their side. If plastic and glass sample containers are used, alternate the placement of each type of container within the cooler so that glass bottles are not placed side by side.

Insert cooler temperature blanks if required.

Place additional vermiculite, bubble wrap, and/or styrofoam pellet packing material throughout the voids between sample containers within each cooler to a level which meets the approximate top of the sample containers. Packing material may require tamping by hand to reduce the potential for settling.

Place cubed ice or cold packs in heavy duty Zip-lock type plastic bags, close the bags, and distribute the packages in a layer over the top of the samples. Cubed ice should be double-bagged to prevent leakage. Loose ice should never be used. Cold packs should be used only if the samples are chilled before being placed in the cooler.

Add additional bubble wrap/styrofoam pellets or other packing materials to fill the balance of the cooler or container.

Obtain two pieces of chain of custody tape as shown in Figure 2 and enter the custody tape numbers in the appropriate place on the chain-of-custody form. Sign and date the chain-of-custody tape.

Complete the chain-of-custody form. If shipping the samples involves use of a third party commercial carrier service, sign the chain-of-custody record thereby relinquishing custody of the samples. Shippers should not be asked to sign chain of custody records. If a laboratory courier is used, or if samples are transported to the laboratory, the receiving party should accept custody and sign the chain-of-custody records. Remove the last copy from the form and retain it with other field notes. Place the original (with remaining copies) in a Zipper-lock type plastic bag and tape the bag to the inside lid of the cooler or shipping container.

Close the top or lid of the cooler or shipping container.

Place the chain of custody tape at two different locations (i.e., one tape on each side) on the cooler or container lid and overlap with transparent packaging tape.

Packaging tape should be placed entirely around the sample shipment containers. A minimum of two full wraps of packaging tape will be placed at least two places on the cooler.

Repeat the above steps for each cooler or shipping container.

**5.4** Sample Shipping Method

Packaged sample coolers should be shipped using one of the following options:

**5.4.1** Hand Delivery

When a project member is transporting samples by automobile to the laboratory, the cooler should only be sealed with tape. In these cases, chain-of-custody will be maintained by the person transporting the sample and chain-of-custody tape need not be used. Chain-of-custody records should be relinquished upon delivery and a copy of the record retained in the project file.

**5.4.2** Laboratory Courier

Laboratory couriers are usually employees of the analytical laboratory receiving the samples. As such, they will accept custody of the samples and must be asked to sign the chain-of-custody records. Chain-of-custody records do not need to be sealed in the cooler although it is recommended that the coolers be sealed with tape. All other packaging requirements generally apply unless otherwise specified in the SAP.

If the laboratory courier is not authorized to accept custody of the samples, or if the requirements of the project plan preclude transfer to the laboratory courier, samples will be handled as described below in Section 5.4.3.

**5.4.3** Third Party Courier

If overnight shipment is required, a third party package delivery service should be used. Transport the cooler to the package delivery service office or arrange for package pick-up at the site. Fill out the appropriate shipping form or airbill and affix it to the cooler. Some courier services may use multi-package shipping forms where only one form needs to be filled out for all packages going to the same destination. If not, a separate shipping form should be used for each cooler. Keep the receipt for package tracking purposes should a package become lost. Please note that each cooler also requires a shipping label which indicates point of origin and destination. This will aid in recovery of a lost cooler if a shipping form gets misplaced. Never leave coolers unattended while waiting for package pick-up. Airbills or waybills will be maintained as part of the custody documentation.

**5.5** Sample Receipt

Upon receipt of the samples, the analytical laboratory will open the cooler or shipping container and will sign "received by laboratory" on each chain-of-custody form. The laboratory will verify that the chain-of-custody tape has not been broken previously and that the tape number corresponds with the number on the chain-of-custody record. The laboratory will note the condition of the samples upon receipt and will identify any discrepancies between the contents of the cooler and chain-of-custody. The analytical laboratory will then forward the back copy of the chain-of-custody record to the project manager to indicate that sample transmittal is complete.

## 6.0 Quality assurance / quality control

Sampling personnel should follow specific quality assurance guidelines as outlined in the site-specific work plan or QAPP. Proper quality assurance requirements should be provided which will specify sample packaging and shipment requirements if variations to the indicated procedures are necessary on a particular project.

The potential for samples to break during transport increases greatly if individual containers are not snugly packed into the cooler. Completed coolers may be lightly shake-tested to check for any loose bottles. The cooler should be repacked if loose bottles are detected.

Environmental samples are generally shipped so that the samples are maintained at a temperature of approximately 4°C. Temperature blanks may be required for some projects as a quality assurance check on shipping temperature conditions. These blanks usually are supplied by the laboratory and consist of a 40-ml vial or plastic bottle filled with tap water. Temperature blanks should be placed near the center of the cooler.

## 7.0 Data and records management

Documentation supporting sample packaging and shipment generally consists of chain-of-custody records and shipping records. In addition, a description of sample packaging procedures will be written in the field project notebook. All documentation will be retained in the project files following project completion.

## 8.0 Personnel qualifications and training

Sample packaging and shipment is a relatively simple procedure requiring minimal training and a minimal amount of equipment. It is, however, recommended that initial attempts be supervised by more experienced personnel. Sampling technicians should be health and safety certified as specified by OSHA (29 CFR 1910.120(e)(3)(i)) to work on sites where hazardous waste materials are considered to be present.

**8.1** Sampling Technician

It is the responsibility of the sampling technician to be familiar with the procedures outlined within this POP and with specific sampling, quality assurance, and health and safety requirements outlined within the project-specific plans. The sampling technician is responsible for proper packaging and shipment of environmental samples and for proper documentation of sampling activities for the duration of the sampling program.

**8.2** Sampling Coordinator

Large sampling programs may require additional support personnel such as a sampling coordinator. The sampling coordinator is responsible for providing management support such as maintaining an orderly sampling process, providing instructions to sampling technicians regarding sampling locations, and fulfilling sample documentation requirements, thereby allowing sampling technicians to collect samples in an efficient manner.

**8.3** Project Manager

The project manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources, and guidance necessary to perform the activities in accordance with the project plan and this POP. The project manager is also responsible for ensuring that proper arrangements have been made with the designated analytical laboratory. These arrangements include, but are not necessarily limited to, subcontractor agreements, analytical scheduling, and bottle/cooler orders. The project manager may delegate some of these responsibilities to other project staff.

## 9.0 References

Project Operating Procedure

# Operation and Calibration of a Photoionization Detector

## 1.0 Project Scope and applicability

### 1.1 Purpose and Applicability

This document describes the procedures that will be followed by field staff for operation and calibration of a photoionization detector (PID). The PID is primarily used by AECOM personnel for safety and survey monitoring of ambient air, determining the presence of volatiles in soil and water, and detecting leakage of volatiles.

PIDs routinely used by AECOM personnel include the Photovac Microtip, Thermoelectron 580EZ, and MiniRAE 2000. Personnel responsible for using the PID should first read and thoroughly familiarize themselves with the instrument instruction manual.

### 1.2 Principle of Operation

The PID is a non-specific vapor/gas detector. The unit generally consists of a hand-held probe that houses a PID, consisting of an ultraviolet (UV) lamp, two electrodes, and a small fan which pulls ambient air into the probe inlet tube. The probe is connected to a readout/control box that consists of electronic control circuits, a readout display, and the system battery. Units are available with UV lamps having an energy from 9.5 electron volts (eV) to 11.7 eV.

The PID analyzer measures the concentration of trace gas present in the atmosphere by photoionization. Photoionization occurs when an atom or molecule absorbs a photon of sufficient energy to release an electron and become a positive ion. This will occur when the ionization potential of the molecule (in electron volts (eV)) is less than the energy of the photon. The source of photons is an ultraviolet lamp in the probe unit. Lamps are available with energies ranging from 9.5 eV to 11.7 eV. All organic and inorganic vapor/gas compounds having ionization potentials lower than the energy output of the UV lamp are ionized and the resulting potentiometric change is seen as a positive reading on the unit. The reading is proportional to the concentration of organics and/or inorganics in the vapor.

Sample gases enter the probe through the inlet tube and enter the ion chamber where they are exposed to the photons emanating from the UV lamp. Ionization occurs for those molecules having ionization potentials near to or less than that of the lamp. A positive- biased polarizing electrode causes these positive ions to travel to a collector electrode in the chamber. Thus the ions create an electrical current which is amplified and displayed on the meter. This current is proportional to the concentration of trace gas present in the ion chamber and to the sensitivity of that gas to photoionization.

In service, the analyzer is first calibrated with a gas of known composition equal to, close to, or representative of that to be measured. Gases with ionization potentials near to or less than the energy of the lamp will be ionized. These gases will thus be detected and measured by the analyzer. Gases with ionization potentials greater than the energy of the lamp will not be detected. The ionization potentials of the major components of air, i.e., oxygen, nitrogen, and carbon dioxide, range

from about 12.0 eV to 15.6 eV and are not ionized by any of the lamps available. Gases with ionization potentials near to or slightly higher than the lamp are partially ionized, with low sensitivity.

**1.3** Specifications

Refer to the manufacturer's instructions for the technical specifications of the instrument being used. The operating concentration range is typically 0.1 to 2,000 ppm isobutylene equivalent.

## 2.0 Health and safety considerations

The health and safety considerations for the site, including both potential physical and chemical hazards, will be addressed in the site-specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

Only PIDs stamped Division I Class I may be used in explosive atmospheres. Refer to the project HASP for instructions pertaining to instrument use in explosive atmospheres.

## 3.0 Interferences

Regardless of which gas is used for calibration, the instrument will respond to all analytes present in the sample that can be detected by the type of lamp used in the PID.

Moisture will generate a positive interference in the concentration measured for a PID and is characterized by a slow increase in the reading as the measurement is made. Care must be taken to minimize uptake of moisture to the extent possible. Refer to the manufacturers' instructions for care, cleaning, and maintenance.

Uptake of soil into the PID must be avoided as it will compromise instrument performance by blocking the probe, causing a positive interference, or dirtying the PID lamp. Refer to the manufacturers' instructions for care, cleaning, and maintenance.

The user should listen to the pitch of the sampling pump. Any changes in pitch may indicate a blockage and corrective action should be initiated.

## 4.0 Equipment and materials

- Calibration Gas: Compressed gas cylinder of isobutylene in air or similar stable gas mixture of known concentration. The selected gas should have an ionization potential similar to that of the vapors to be monitored, if known. The concentration should be at 50-75% of the range in which the instrument is to be calibrated.

- Regulator for calibration gas cylinder
- Approximately 6 inches of Teflon® tubing
- Tedlar bag (optional)
- Commercially-supplied zero grade air (optional)
- "Magic Marker" or “Sharpie” or other waterproof marker
- Battery charger
- Moisture traps
- Spare lamps
- Manufacturer’s instructions
- Field data sheets or logbook/pen

## 5.0 Procedures

### **5.1** Preliminary Steps

Preliminary steps (battery charging, check-out, calibration, maintenance) should be conducted in a controlled or non-hazardous environment.

### **5.2** Calibration

The PID must be calibrated in order to display concentrations in units equivalent to ppm. First a supply of zero air (ambient air or from a supplied source), containing no ionizable gases or vapors is used to set the zero point. A span gas, containing a known concentration of a photoionizable gas or vapor, is then used to set the sensitivity.

Calibrate the instrument according to the manufacturer’s instructions. Record the instrument model and identification number, the initial and adjusted meter readings, the calibration gas composition and concentration, and the date and the time in the field records.

If the calibration cannot be achieved or if the span setting resulting from calibration is 0.0, then the lamp must be cleaned (Section 5.4).

### **5.3** Operation

Turn on the unit and allow it to warm up (minimum of 5 minutes). Check to see if the intake fan is functioning; if so, the probe will vibrate slightly and a distinct sound will be audible when holding the probe casing next to the ear. Also, verify on the readout display that the UV lamp is lit.

Calibrate the instrument as described in Section 5.2, following the manufacturer’s instructions. Record the calibration information in the field records.

The instrument is now operational. Readings should be recorded in the field records.

When the PID is not being used or between monitoring intervals, the unit may be switched off to conserve battery power and UV lamp life; however, a "bump" test should be performed each time the unit is turned on and prior to taking additional measurements. To perform a bump test, connect the outlet tubing from a Tedlar bag containing a small amount of span gas to the inlet tubing on the unit and record the reading. If the reading is not within the tolerance specified in the project plan, the unit must be recalibrated.

At the end of each day, recheck the calibration. The check will follow the same procedures as the initial calibration (Section 5.2) except that no adjustment will be made to the instrument. Record the information in the field records.

Recharge the battery after each use (Section 5.4).

When transporting, ensure that the instrument is packed in its stored condition in order to prevent damage.

### **5.4** Routine Maintenance

Routine maintenance associated with the use of the PID includes charging the battery, cleaning the lamp window, replacing the detector UV lamp, replacing the inlet filter, and replacing the sample pump. Refer to the manufacturer's instructions for procedures and frequency.

All routine maintenance should be performed in a non-hazardous environment.

### **5.5** Troubleshooting Tips

One convenient method for periodically confirming instrument response is to hold the sensor probe next to the tip of a magic marker. A significant reading should readily be observed.

Air currents or drafts in the vicinity of the probe tip may cause fluctuations in readings.

A fogged or dirty lamp, due to operation in a humid or dusty environment, may cause erratic or fluctuating readings. The PID should never be operated without the moisture trap in place.

Moving the instrument from a cool or air-conditioned area to a warmer area may cause moisture to condense on the UV lamp and produce unstable readings.

A zero reading on the meter should not necessarily be interpreted as an absence of air contaminants. The detection capabilities of the PID are limited to those compounds that will be ionized by the particular probe used.

Many volatile compounds have a low odor threshold. A lack of meter response in the presence of odors does not necessarily indicate instrument failure.

When high vapor concentrations enter the ionization chamber in the PID the unit can become saturated or "flooded". Remove the unit to a fresh air environment to allow the vapors to be completely ionized and purged from the unit.

## 6.0 Quality assurance / quality control

The end use of the data will determine the quality assurance requirements that are necessary to produce data of acceptable quality. These quality assurance requirements will be defined in the site-specific workplan or Sampling and Analysis Plan (SAP), hereafter referred to as the project plan.

Calibration of the PID will be conducted at the frequency specified in the project plan. In the absence of project-specific guidance, calibration will be performed at the beginning of each day of sampling and will be checked at the end of the sampling day or whenever instrument operation is suspect. The PID will sample a calibration gas of known concentration. The instrument must agree with the calibration gas within ±10%. If the instrument responds outside this tolerance, it must be recalibrated.

Checks of the instrument response (Section 5.5) should be conducted periodically and documented in the field records.

## 7.0 Data and records management

Safety and survey monitoring with the PID will be documented in a bound field logbook, or on standardized forms, and retained in the project files. The following information is to be recorded:

- Project name and number.
- Instrument manufacturer, model, and identification number.
- Operator's signature.
- Date and time of operation.
- Calibration gas used.
- Calibration check at beginning and end of day (meter readings before adjustment).
- Span setting after calibration adjustment.
- Meter readings (monitoring data obtained).
- Instances of erratic or questionable meter readings and corrective actions taken.
- Instrument checks and response verifications – e.g., battery check, magic marker response (Section 5.5) or similar test.

## 8.0 Personnel qualifications and training

The project manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources, and guidance necessary to perform the measurements in accordance with this POP and the project plan.

The field operator is responsible for verifying that the PID is in proper operating condition prior to use and for implementing the calibration and measurement procedures in accordance with this POP and the project plan.

Project Operating Procedure

# Surface and Subsurface Soil Sampling Procedures

## 1.0 Project Scope and applicability

This project operating procedure (POP) is applicable to soil sampling. The procedure includes surface and subsurface sampling by various methods using hand auguring, test pit, direct-push, and split-spoon equipment. The procedure includes soil sampling for volatile organic compounds (VOCs). For project specific information (e.g. sampling depths, equipment to be used, and frequency of sampling), refer to the Quality Assurance Project Plan (QAPP) and/or Work Plan, which take precedence over these procedures.

Surface soil sampling, typically considered to be up to two feet below ground surface by EPA standards, is typically accomplished using hand tools such as shovels or hand augers. Test pit samples are considered subsurface samples, although normally collected via hand tools similar to surface soil sampling or by excavation machinery. Direct-push and split-spoon sampling offer the benefit of collecting soil samples from a discrete or isolated subsurface interval, without the need of extracting excess material above the target depth. These methods dramatically reduce time and cost associated with disposal of material from soil cuttings when compared to test pit sampling. In addition, direct-push and split-spoon sampling methods can obtain samples at targeted intervals greater than 15 feet in depth, allowing for discrete depth soil sampling while speeding up the sampling process. Direct-push methods work best in medium to fine-grained cohesive materials such as medium to fine sands, silts, and silty clay soils. Split-spoon sampling works well in all types of soil, but is somewhat slower than direct-push methods. Samples are composited so that each sample jar to be analyzed contains a homogenized representative portion of the interval samples. Due to potential loss of analytes, samples for volatile analysis are not composited. Samples for chemical analysis can be collected by any of the above-mentioned sampling methods, as disturbed soil samples. Undisturbed samples are collected, sealed, and sent directly to the laboratory for analysis. For undisturbed samples, the samples are not homogenized.

## 2.0 Health and safety considerations

All calibration, maintenance and servicing of soil sampling equipment and instrumentation should be performed in a safe area, away from hazardous locations.

Refer to the Site-Specific Health and Safety Plan for health and safety issues and equipment/instrumentation needed. General health and safety equipment includes a combustible gas indicator (CGI), photo/flame ionization detector (PID/FID), tyvek, gloves, safety glasses, and steel-toe boots.

The Site-Specific Health and Safety Plan should be followed during all site activities. Health and safety meetings should be held each day prior to the commencement of activities.

Before soil sampling commences, appropriate entities (e.g. DigSafe, New Jersey Call Before You Dig, local public works departments, company facilities, etc.) must be contacted to assure the anticipated soil sampling locations are marked for utilities, including electrical, telecommunications, water, sewer,

and gas. These entities will be notified by the drilling contractor at least three, but not more than ten business days prior to the start of drilling. Prior to conducting any intrusive operations, existing drawings and other available documentation will be reviewed to evaluate whether potential conflicts with underground utilities exist. If any doubt exists regarding the potential presence of subsurface utilities, a professional utility locating service will be retained to conduct surveys to clear proposed drilling locations. A variety of techniques are available to locate utilities, including ground penetrating radar, electromagnetic conductivity, radio frequency, audio frequency, and passive electric. The efficacy of each technique is dependent on the material used to construct the utility, type of utility, number and type of nearby utilities, and many other factors. As such, it is common practice to use more than one utility locating technique. The requirements for utility location and appropriate techniques will be determined once available information is gathered and evaluated. Soil boring, sampling, and monitoring well locations will be adjusted to avoid underground and overhead utilities. As an added precaution, vacuum boring to a depth of four feet or to the expected invert depth of the deepest utility at any given soil boring or well location may be conducted. However, if vacuum boring is required at certain locations, collection of shallow soil samples for laboratory analysis in the vacuumed zone will still be undertaken from the sidewall area of the vacuumed zone to ensure that shallow surface soil samples will be collected at all proposed off-site investigation locations. The shallow surface soil samples will be collected according the General Soil Sampling procedures in Section 5.1 and Surface Soil Sampling procedures in Section 5.2. All underground utility identification will be performed in accordance with AECOM SH&E SOP No. 726, located in the site-specific Health and Safety Plan (HASP).

## 3.0 Interferences

Low recovery of soil from sampling equipment will prevent an adequate representation of the soil profile and sufficient amount of soil sample. If low recovery is a problem, the hole may be offset and re-advanced, terminated, or continued using a larger diameter sampler.

Asphalt in soil samples can cause false positive results for hydrocarbons. To ensure samples are free of asphalt, do not collect sample from soil with possible asphalt. Note the sampling depth(s) and the depths at with the presence of asphalt are suspected.

Instrumentation interferences addressed in POPs for Calibration of the PID, Headspace Screening for Total Volatile Organics, and Equipment Decontamination Procedures must also be considered.

Cross contamination from sampling equipment will be prevented by using sampling equipment constructed of stainless steel that is adequately decontaminated between samples.

## 4.0 Equipment and materials

The depth at which samples will be collected and the anticipated method of sample collection (direct-push, split-spoon, hand auger, shovel, or test pits) will be presented in the QAPP and/or Work Plan.

The following details equipment typically needed for soil sampling, based on the various methods. See the QAPP and/or Work Plan for specific detail of equipment and supply needs.

Depending on the nature of suspected contamination, field screening instrumentation may be used to direct sampling. Appropriate instrumentation and calibration standards should be available. If volatile organic contaminants are suspected and a PID will be used, refer to the equipment and instrumentation listed in the POP PPG 004 Operation and Calibration of a Photoionization Detector. Equipment in this POP includes but is not limited to:

- PID
- Calibration gas
- Tedlar® gas bags (for calibration)

If field screening methods include jar headspace screening for volatile organics, refer to the equipment and procedure in the POP for Headspace Screening for Total VOCs. Equipment in this POP includes but is not limited to:

- Clean soil ("drillers jars") jars
- Aluminum foil

Appropriate decontamination procedures must be followed for sampling equipment. Refer to POP PPG 014 Decontamination of Field Equipment for the proper decon procedures.

The following general equipment is needed for all soil sampling, regardless of method:

- Stainless steel bowls
- Stainless steel trowels
- Appropriate sample containers for laboratory analysis
- CGI (as necessary – i.e. sites where explosive gasses may be encountered)
- Personal Protective Equipment (PPE)
- Log Book
- Cooler and ice for preservation
- Stakes and flagging to document sampling location

The following additional equipment is needed for volatile organic sampling:

- Electronic pan scale and weights for calibration
- Syringes or other discrete soil core samplers

The following additional equipment may be needed for surface and test pit soil sampling:

- Hand Auger

The following additional equipment may be needed for soil sampling from split-spoon equipment:

- Tape measure or folding carpenter's rule for recording the length of soil recovered in the split-spoon.

All subsurface drilling equipment will be provided and maintained by the subcontractor.

## 5.0 Procedures

**5.1** General Soil Sampling Procedure for All Soil Sampling Methods

1. Record the weather conditions and other relevant on-site conditions.
2. Select the soil sampling location, clear vegetation if necessary, and record the sampling location identification number and pertinent location details.
3. Verify that the sampling equipment is properly decontaminated, in working order, and situated at the intended sampling location.
4. Place polyethylene sheeting on the ground and assemble all necessary sampling equipment on top of it. Cover surfaces onto which soils or soil samplers will be placed (i.e. tables with polyethylene sheeting).
5. Follow the appropriate procedures listed below for either surface, split-spoon, direct push, or test pit sample collection (5.2, 5.3, 5.4, and 5.5 respectively).
7. For projects located in New Jersey, see Section 5.6 for New Jersey-specific requirements for soil samples collected for volatile organics analysis.
6. Collect soil samples according to procedures listed in Section 5.7 depending on project specific analyses.
7. Record date/time, sample ID, and sample descriptions in the field logbook for field form. A sketch or description of the location should also be recorded so the sample location can be re-constructed.
8. Immediately label (and tag if required) the sample containers and place them on ice, if required for preservation. Complete the COC form(s) as soon as possible.
9. Dispose of all excess excavated soil in accordance with the site-specific QAPP and/or Work Plan. Soils may either be segregated based on level of contamination, stockpiled, drummed for disposal, or put back into the hole from which the soil came.
10. Upon completion, clearly label a wooden stake or pin flag with indelible ink and stake or flag the sampling location.

11. Decontaminate the sampling equipment according to POP PPG 014 Decontamination of Field Equipment.

**5.2** Surface Soil Sampling

The following procedures are to be used to collect surface soil samples. Surface soils are considered to be soils that are up to one (1) foot below ground surface, though state regulations and project objectives may define surface soils differently; therefore, the QAPP and/or Work Plan should be consulted for direction on the depth from which to collect the surface soil samples. Sampling and other pertinent data and information will be recorded in the field logbook and/or on field forms. Photographs will be taken as needed or as specified in the QAPP and/or Work Plan.

1. Gently scrape any vegetative covering until soil is exposed. Completely remove any pavement.
2. Remove soil from excavation with a trowel, hand auger, or shovel. Put soils within the sampling interval in a stainless steel bowl for homogenizing. Monitor the excavation as required in the site-specific HASP and/or QAPP and/or Work Plan (i.e., PID).

The criteria used for selecting surface soil locations for sampling may include the following:

- Visual observations (soil staining, fill materials)
- Other relevant soil characteristics
- Site features
- Screening results
- Predetermined sampling approach (i.e. grid or random)
- Sampling objectives as provided in the QAPP and/or Work Plan

3. For VOC analyses, collect representative soil samples directly from the recently-exposed sidewall of the excavation using a syringe or other soil coring device (e.g., TerraCore®, EnCore®). Follow procedures in Section 5.7.1 or 5.7.2 for VOC sampling.
4. Collect sufficient soil to fill all remaining sample jars into a stainless steel bowl. Homogenize the soil samples to obtain a uniform soil composition which is representative of the total soil sample collected according to the following procedure:
    a) Remove all rocks and non-soil objects using a stainless steel spoon or scoop. However, if the soils to be sampled contain chromite ore processing residue (COPR) nodules or chromate chemical production waste (CCPW) materials, **do not** remove these CCPW “non-soil objects” and document their presence in the field logbook.
    b) Form a cone shaped mound with the sample material, then flatten the cone and split the sample into quarters.

c) Use the stainless steel spoon/scoop to mix the quarter samples that are opposite.

d) After mixing the opposite quarters, reform the cone shaped mound.

e) Repeat this procedure a minimum of five (5) times, removing any non-soil objects and breaking apart any clumps.

**5.3** Split-Spoon Sampling

1. At each boring location, the frequency and depth of split-spoon samples will be determined from the QAPP and/or Work Plan. Split-spoon samples may be collected continuously, intermittently, or from predetermined depths.
2. Standard penetration tests will be conducted according to ASTM D1586-99, Standard Test Method for Penetration Test and Split-Barrel Sampling of Soils to record the number of hammer blows required to advance the sampler each 6 inches of depth in the boring log.
3. Split-spoon samplers shall be driven into undisturbed soil by driving the spoon ahead of the drill augers/casing. In cohesive soils, or soils where the borehole remains open (does not collapse), two split-spoon samples may be taken prior to advancing the augers/casing.
4. After split-spoons are retrieved, open the split-spoon and measure the recovery of soil. If a PID will be used for screening, immediately scan the recovered sample for VOCs using a PID/FID. Scan the recovered soil by making a hole in the soil and placing the PID in or very close to the hole. Be very careful not to get soil on the tip of the PID. Take these PID scan readings every 6 inches along the split-spoon. Note any staining and/or presence of water. Record the highest PID reading and the depth at which it was observed along with other observations. If the project is in New Jersey, see Section 5.6 for state-specific procedures on determining where to collect VOC samples. All VOC samples should be collected (see Section 5.7.1 and 5.7.2) prior to logging the sample.
5. If headspace screening for VOCs is required in the QAPP and/or Work Plan, collect a soil sample and perform headspace screening according to the POP for Headspace Screening for Total VOCs.
6. Soils collected using the split-spoon sampler will be logged by the AECOM field representative using the procedure described in ASTM D2488-00 Standard Practice for Description and Identification of Soils. In addition to the description of the soils, blow counts, sample recovery, PID readings (headspace), and the depth to water will also be recorded.
7. Collect the remainder of the sample volume required into a stainless steel bowl. Homogenize the soil so the material is uniform in composition and representative of the total soil sample collected. Follow homogenizing techniques as described in Section 5.2.
8. The QAPP and/or Work Plan may specify that intervals to be sent to the laboratory be determined by visual observation and/or highest PID screening or headspace results,

which can only be determined once the boring is complete. In this instance, a VOC sample should be collected at each interval. The remainder of the soil from that interval will be set aside in a clearly labeled stainless steel bowl covered with aluminum foil. Once the boring has been completed and the sample interval has been determined, the remainder of the soil can be homogenized according to Section 5.2 and submitted for laboratory analysis.

9. Once a boring is complete and all required samples have been collected, the boring may be filled or a monitoring well or piezometer may be installed. Borings must be completed as specified in the QAPP and/or Work Plan.

**5.4** Direct Push Sampling

At each boring location, the frequency of direct-push samples will be determined from the QAPP and/or Work Plan. Typically, samples with direct-push equipment are collected in 4 ft intervals.

1. Sample using either 2' or 4' Macro-Core samplers with acetate liners to obtain discrete soil samples at specific depths.
2. Cut open the acetate liner, and immediately scan the recovered sampler for VOCs using a PID/FID. Note any staining and/or presence of water. Record the highest PID reading and the depth at which it was observed along with other observations. If the project is in New Jersey, see Section 5.6 for state-specific procedures on determining where to collect VOC samples. All VOC samples should be collected (see Section 5.7.1 and 5.7.2) prior to logging the sample.
3. If required in the QAPP and/or Work Plan, collect a soil sample and perform headspace screening according to the POP for Headspace Screening for Total VOCs.
4. Soils collected using the direct-push sampler will be logged by the AECOM field representative using the procedure described in ASTM D2488-00 Standard Practice for Description and Identification of Soils. In addition to the description of the soils and sample recovery, PID readings (headspace), and the depth to water will also be recorded.
5. Collect the remainder of the sample into a stainless steel bowl. Homogenize the soil collected so that the material is uniform in composition and representative of the total soil sample collected. Follow homogenizing techniques as described in Section 5.2.
6. Once a boring is complete and all required samples have been collected, the boring may be filled or a monitoring well or piezometer may be installed. Borings must be completed as specified in the QAPP and/or Work Plan.

**5.5** Test Pit Sampling

1. Excavate the test pit to the desired depth.
2. Using the excavator bucket, collect soil samples as specified in the QAPP and/or Work Plan. Collect a sample and perform screening analyses as required by the QAPP and/or Work Plan. If VOCs contamination is suspected,

perform headspace screening according to the POP for Headspace Screening for Total VOCs.

3. Collect the sample from center of the bucket to avoid potential contamination from the bucket.
4. VOC samples should also be collected from an undisturbed section soil in the excavator bucket. The top layer of exposed soil should be scraped away just prior to collecting the VOC samples. VOC samples should be collected according to the procedures in Section 5.7.1 and 5.7.2.
5. Collect the remainder of the sample volume required into a stainless steel bowl. Homogenize the soil so the material is uniform in composition and representative of the total soil sample collected. Follow homogenizing techniques as described in section 5.2.
6. Dispose of all excavated soil according to the QAPP and/or Work Plan.

**5.6** Special considerations for projects in New Jersey

**5.6.1** All soil samples to be analyzed for volatile organics shall be collected as follows:

- A bulk sampling device that will collect an intact core (e.g., split-spoon) shall be used to minimize contaminant loss during sampling.
- Each core shall be field screened with a properly calibrated direct reading instrument equipped with a PID, flame ionization detector (FID), or other suitable instrument capable of detecting the contaminants pursuant to N.J.A.C. 7:26E-2.1(b) to select samples for volatile organics analysis using the following criteria if field measurement readings are above background:
    - The coring shall be extended until either background readings are achieved, ground water is encountered, or bedrock is encountered; and
    - An undisturbed sample from the six-inch interval registering the highest field measurement reading shall be collected, at a minimum, using the appropriate sample collection method and sampling device for volatile organics analysis pursuant to the requirements specified in N.J.A.C. 7:26E-2.1(a)4.
- If all intervals register the same field measurement reading or all field measurement readings do not exceed background:
    - The coring shall be extended to ground water, bedrock, or 10 feet, whichever is encountered first;
    - One undisturbed sample at a minimum, from the six-inch interval at the bottom of the soil boring shall be collected, using the appropriate sample collection method and sampling device for volatile organics analysis pursuant to the requirements specified in N.J.A.C. 7:26E-2.1(a)4; and

- Contaminants that cannot be detected with field-screening instruments shall be sampled in accordance with the requirements at N.J.A.C. 7:26E-3.4(a).

- In all cases, samples shall be collected in discrete six inch increments. If more or less than a six inch increment is sampled because of poor sample recovery or other field logistical problems, an explanation shall be provided in the soil log.

**5.7** Sample Collection Methods

**5.7.1** Volatile Organics Sampling – Closed System Vials with Organic Free Water (low-level) and Methanol (high level)

For soils collected for analyses of volatile organics, including Volatile Petroleum Hydrocarbons (VPH) or other purgable compounds, a closed system is maintained. From collection through analysis, the sample bottles are not opened. The bottle kit for a routine field sample for these analyses will typically include four 40-mL VOA vials and one soil jar. Two 40-mL VOA vials will contain 5 mL organic free water (OFA) and magnetic stir bars (i.e., low level vials), and two VOA vials will contain 15 mL methanol with no magnetic stir bar (i.e., high level vial). These vials are provided by the laboratory and are pre-weighed. No sample labels are affixed to the VOA vials, as addition of a label would alter the vial weight. All information is recorded directly on the VOA vial using indelible marker. The soil jar is provided for percent solids determination. For VOC or VPH analyses, samples are collected prior to sample homogenization. Collect the VOC sample in accordance with the procedure described below.

1. Prior to sampling, weigh the 40-mL VOA vials received from the laboratory. Record this weight to the nearest 0.1 gram. This weight will be used to determine if the proper amount of soil has been added to the vial. In addition, the weight should be within 0.2 grams of the tare weight on the sample label. If the weight is off by more than 0.2 grams, do not use this vial as some of the OFA may have been lost.

2. Determine the soil volume necessary for the required sample weight, typically 5 grams:

   a) Prepare a 5 mL sampling corer (e.g., Terra Core®) or cut-off plastic syringe.

   b) Tare the sampler by placing it on the scale, and zeroing the scale.

   c) Draw back the plunger to the 5 gram mark or 5mL (5cc) mark on cut-off syringe, and insert the open end of the sampler into an undisturbed area of soil with a twisting motion, filling the sampler with soil. Note the location of the plunger with respect to the milliliter (cc) or other graduation printed on the sampler.

d) Weigh the filled sampler, and remove or add soil until the desired weight is obtained. Note the location of the plunger which corresponds to this weight. Do not use this sample for laboratory analysis.

3. Once the required soil volume has been determined, pull the plunger back to this mark and hold it there while filling the syringe for each sample.

4. Collect 5 grams of soil using the cut-off syringe or Terra Core® sample device. Extrude the 5-grams of soil into one of the low level 40-mL VOA vials. Quickly wipe any soil from the threads of the VOA vial with a clean Kimwipe® and immediately close the vial. It is imperative that the threads be free from soil or other debris prior to replacing the cap on the vial in order to maintain the closed system necessary for the analysis.

5. Gently swirl the vial so that all of the soil is fully wedded with the preservative.

6. Weigh the 40 mL vial with the sample contained. Sample weight should be within 0.5 grams (±10%) of the target weight. Record the sample weight.

7. Fill the other low level 40 mL VOA vial in this manner,

8. Repeat the process for the high level VOA vials.

NOTE: Depending on the laboratory, some high level VOA vials contain 10 mL or 15 mL of methanol. If this is the case, either 10 grams total or 15 grams total, respectively, should be extruded into the high level VOA vial (i.e., 2 or 3 Terra Core® volumes). In other words, the mass of soil in grams should be identical to the volume of methanol in mL (i.e., 1:1 ratio of soil to methanol).

9. Collect any additional QC sample collected (e.g., field duplicate, MS, and MSD) in the same manner as above.

10. Fill the 4-oz glass jar with soil from the same area for percent moisture determination.

**5.7.2** Volatile Organics Sampling – En Core® Samplers

This preservation and sampling method employs the use of a small-diameter core sampler known as the En Core® sampler. The En Core® sampler is a one-time-use, volumetric sampling, storage and transportation device. It is designed to collect and store soil samples for transportation to the laboratory.

Soil should be collected using the En Core® sampler in accordance with the manufacturer's recommendations. A specially designed "T" handle, available from the manufacturer, is used to push the En Core® sampler into the soil matrix and to lock the sampler after collection. A copy of the manufacturer's instructions is provided as Attachment 2 of this POP.

A minimum of three (3) individual 5 gram En Core® samplers must be collected for each soil sample. Upon sample collection, label each En Core® sampler cap with the label provided by the manufacturer and return it to the airtight, resealable foil package. The 4-oz glass jar must be filled with soil from the same area from which

the En Core® samplers were collected for the percent moisture determination. En Core® samplers should be iced (cooled to 4°C [+ 2°C]) or frozen (-7°C and -15°C) for later shipment to the laboratory. En Core® samplers can be shipped directly to the laboratory for VOC analysis; however, laboratory must extrude the soil from the En Core® sampler and analyze, chemically preserve or freeze the soil within 48 hours of sample collection. The soil samples must be extruded from the En Core® sampler into appropriate sample containers using a specially designed "T" handle push-rod tool available from the manufacturer. Soil cannot be scooped out of the En Core® sampler using a trowel or spatula as this can cause a significant loss of VOCs. The holding time for soil stored in an En Core® sampler can be extended if the soil is extruded by the laboratory within 48 hours to a sealed vial and frozen or chemically preserved until actual analysis. This method is appropriate for low- and medium-level analysis under USEPA CLP SOW and low and high-level analysis for USEPA SW846 Methodologies.

En Core® samplers must be stored in a contaminant free environment before use and during shipment. It is the responsibility of the field sampling team and sample container provider (i.e., the laboratory) to ensure contaminant free sample container integrity.

**5.7.3** Soil Sampling Method (All other analyses except VOC/VPH)

When all the required soil for a sampling location has been obtained, the soil can be homogenized as described in section 5.2. Collect sufficient volume to fill all of the remaining sample containers at least ¾ full for all other analyses. Homogenize the soil in a decontaminated stainless steel bowl, removing rocks, sticks, or other non-soil objects (with the exception of COPR nodules and CCPW materials) and breaking apart any lumps of soil prior to filling the remaining sample containers.

NOTE: Soil samples must contain greater than 30% solids for the data to be considered valid.

## 6.0 Quality assurance / quality control

Sampling personnel should follow specific quality assurance guidelines as outlined in the QAPP and/or Work Plan. Proper quality assurance requirements should be provided which will allow for collection of representative samples from representative sampling points. Quality assurance requirements outlined in the QAPP and/or Work Plan typically suggest the collection of a sufficient quantity of field duplicate, field blank, and other samples.

Quality control requirements are dependent on project-specific sampling objectives. The QAPP and/or Work Plan will provide requirements for equipment decontamination (frequency and materials), sample preservation and holding times, sample container types, sample packaging and shipment, as well as requirements for the collection of various quality assurance samples such as trip blanks, field blanks, equipment blanks, and field duplicate samples.

## 7.0 Data and records management

All data and information (e.g., sample collection method used) must be documented on field data sheets, boring logs, or within site log books with permanent ink. Data recorded will include the following:

- weather conditions
- arrival and departure time of persons on site
- instrument type, lamp (PID), make, model and serial number
- calibration gas used
- date, time and results of instrument calibration and calibration checks
- sampling date and time
- sampling location
- samples collected
- sampling depth and soil type
- deviations from the procedure as written
- readings obtained

## 8.0 Personnel qualifications and training

All field staff are required to be OSHA 40-Hour Health and Safety certified with a current annual 8-hour refresher prior to engaging in any field collection activities.

Prior to implementation of these soil sampling procedures, the field sampler will be instructed by a person experienced with these procedures. The field staff will demonstrate to the field team leader the proper set-up, calibration, operation, and routine maintenance of the instrumentation and hand-held equipment, as well as the proper procedures, used to collect soil samples.

## Sampling Procedures

## Using The En Core® T-Handle

*NOTE:*

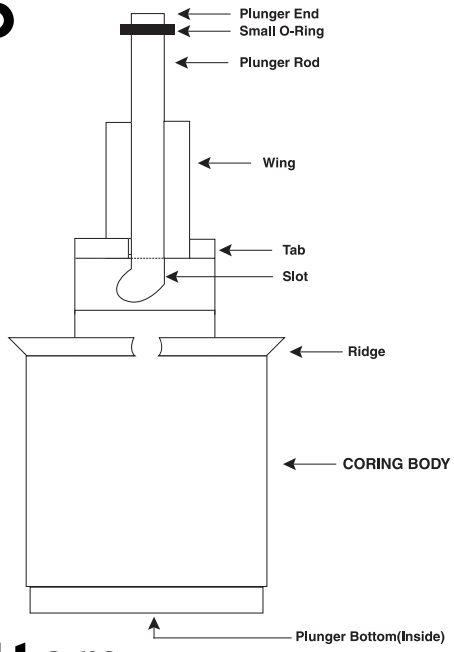
1. En Core® Sampler is a SINGLE USE device. It cannot be cleaned and/or reused.

2. En Core® Sampler is designed to store soil. Do not use En Core Sampler to store solvent or free product!

3. En Core® Sampler must be used with En Core® T-Handle and/or En Core® Extrusion Tool exclusively. (These items are sold separately.)

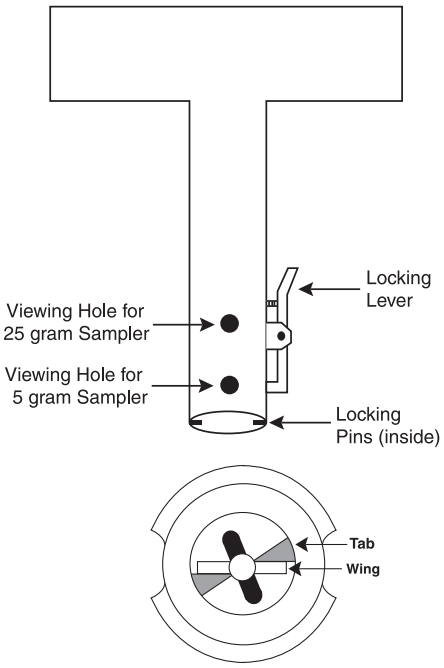
### En Core®

**Top**



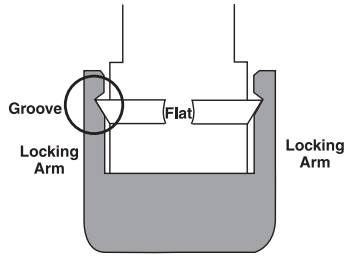
**Bottom**

### En Core® T-Handle



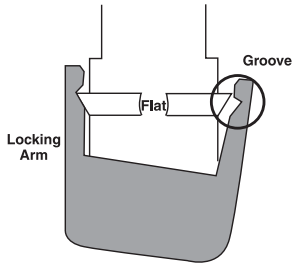
### Sampler Correctly Capped

(Locking arm grooves seated over coring body ridge.)



### Sampler Incorrectly Capped

(Cap appears crooked; locking arm grooves not fully seated over coring body ridge.)



**BEFORE TAKING SAMPLE:**

1. Hold **coring body** and push **plunger rod** down until **small o-ring** rests against **tabs**. This will assure that plunger moves freely.

2. Depress **locking lever** on En Core T-Handle. Place coring body, **plunger end first,** into open end of T-Handle, *aligning the (2)* ***slots*** *on the coring body with the (2)* ***locking pins*** *in the T-Handle*. Twist coring body clockwise to lock pins in slots. Check to ensure Sampler is locked in place. Sampler is ready for use.

**TAKING SAMPLE:**

3. Turn T-Handle with T-up and coring body down. This positions plunger bottom flush with bottom of coring body (ensure that plunger bottom is in position). Using T-Handle, push Sampler into soil until coring body is completely full. When full, small o-ring will be centered in T-Handle **viewing hole**. Remove Sampler from soil. Wipe excess soil from coring body exterior.

4. Cap coring body while it is still on T-handle. *Push* **cap** over **flat** area of **ridge** *and twist* to lock **cap** in place. **CAP MUST BE SEATED TO SEAL SAMPLER (see diagram)**.

**PREPARING SAMPLER FOR SHIPMENT:**

5. Remove the capped Sampler by depressing locking lever on T-Handle while twisting and pulling Sampler from T-Handle.

6. Lock plunger by rotating extended plunger rod fully counter-clockwise until **wings** rest firmly against tabs (see plunger diagram).

7. Attach completed tear-off label (from En Core Sampler bag) to cap on coring body.

8. Return full En Core Sampler to zipper bag. Seal bag and put on ice.

# Disposable En Core® Sampler

## EXTRUSION PROCEDURES

## USING THE En Core® EXTRUSION TOOL

***CAUTION! Always use the Extrusion Tool to extrude soil from the En Core Sampler. If the Extrusion Tool is not used, the Sampler may fragment, causing injury.***

1. To attach En Core Sampler to En Core Extrusion Tool: Depress locking lever on Extrusion Tool and place Sampler, plunger end first, into open end of Extrusion Tool, aligning slots on coring body with pins in Extrusion Tool. Turn coring body clockwise until it locks into place. Release locking lever.

2. Rotate and gently push Extrusion Tool plunger knob clockwise until plunger slides over wings of coring body. (When properly positioned plunger will not rotate further.)

3. Hold Extrusion Tool with capped Sampler pointed upward so soil does not fall out when cap is removed. Remove cap from Sampler by rotating cap until locking arms are aligned with the flat area of ridge and pull cap off. To release soil core push down on plunger knob of En Core Extrusion Tool. Remove and properly dispose of En Core Sampler.

## Warranty and Disclaimers

IMPORTANT: FAILURE TO USE THE EN CORE® SAMPLER IN COMPLIANCE WITH THE WRITTEN INSTRUCTIONS PROVIDED HEREIN VOIDS ALL EXPRESS AND IMPLIED WARRANTIES, INCLUDING WARRANTY OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

**PRINCIPLE OF USE.** The En Core Sampler Cartridge System is a volumetric sampling system designed to collect, store and deliver a soil sample. The En Core Sampler comes in two sizes for sample volumes of approximately 25 or 5 grams. There are four components: the cartridge with a movable plunger; a cap with two locking arms; a T-handle (purchased separately); and an extrusion handle (purchased separately). NOTE: The En Core Sampler is designed to store soil. It is not designed to store solvent or free product.

The soil is stored in a sealed headspace-free state. The seals are achieved by three special Viton® * o-rings, two located on the plunger and one on the cap of the Sampler. At no time and under no condition should these o-rings be removed or disturbed.

**QUALITY CONTROL**. The cartridge is sealed in an airtight package to prevent contamination prior to use. Due to the stringent quality control requirements associated with the use of this system, the disposable cartridge is designed to be used only once.

**WARRANTY**. En Novative Technologies, Inc. ("En Novative Technologies") warrants that the En Core Sampler shall perform consistent with the research conducted under En Novative Technologies' approval, within thirty (30) days from the date of delivery, provided that the Customer gives En Novative Technologies prompt notice of any defect or failure to perform and satisfactory proof thereof. THIS WARRANTY DOES NOT APPLY TO THE FOLLOWING, AS SOLELY DETERMINED BY EN NOVATIVE TECHNOLOGIES: (a) Damage caused by accident, abuse, mishandling or dropping; (b)Samplers that have been opened, taken apart or mishandled; (c)Samplers not used in accordance with the directions; and (d)Damages exceeding the cost of the sampler. Seller warrants that all En Core Samplers shall be free from defects in title. THE FOREGOING WARRANTIES ARE IN LIEU OF ALL OTHER WARRANTIES, WHETHER ORAL, WRITTEN, EXPRESSED, IMPLIED OR STATUTORY, INCLUDING ANY INFORMATION PROVIDED BY SALES REPRESENTATIVES OR IN MARKETING LITERATURE. IMPLIED WARRANTIES OF FITNESS AND MERCHANTABILITY SHALL NOT APPLY. En Novative Technologies' warranty obligations and Customer's remedies, except as to title, are solely and exclusively as stated herein.

**LIMITATION OF LIABILITY.** IN NO EVENT SHALL EN NOVATIVE TECHNOLOGIES BE LIABLE FOR ANTICIPATED PROFITS, INCIDENTAL, SPECIAL OR CONSEQUENTIAL DAMAGES, INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF REVENUE, DOWN TIME, REMEDIATION ACTIVITIES, REMOBILIZATION OR RESAMPLING, COST OF CAPITAL, SERVICE INTERRUPTION OR FAILURE OF SUPPLY, LIABILITY OF CUSTOMER TO A THIRD PARTY, OR FOR LABOR, OVERHEAD, TRANSPORTATION, SUBSTITUTE SUPPLY SOURCES OR ANY OTHER EXPENSE, DAMAGE OR LOSS, INCLUDING PERSONAL INJURY OR PROPERTY DAMAGE. En Novative Technologies' liability on any claim of any kind shall be replacement of the En Core Sampler or refund of the purchase price. En Novative Technologies shall not be liable for penalties of any description whatsoever. In the event the En Core Sampler will be utilized by Customer on behalf of a third party, such third party shall not occupy the position of a third-party beneficiary of the obligation or warranty provided by En Novative Technologies, and no such third party shall have the right to enforce same. All claims must be brought within one (1) year of shipment, regardless of their nature.

Project Operating Procedure

# Monitoring Well Construction and Installation

## 1.0 Project Scope and applicability

### 1.1 Purpose and Applicability

This Project Operating Procedure (POP) provides guidance for installing groundwater monitoring wells. Monitoring wells are installed to monitor the depth to groundwater, to measure aquifer properties, and to obtain samples of groundwater for chemical analysis.

This POP is applicable to installation of single monitoring wells within a borehole. The construction and installation of nested, multilevel or other special well designs is not covered within this POP as these type of wells are not frequently constructed. This POP applies to both overburden and bedrock monitoring wells.

Some states and EPA Regions have promulgated comprehensive guidelines for monitoring well construction and for subsurface investigation procedures. Deviations from this POP to accommodate other regulatory requirements should be reviewed in advance of the field program, should be explained in the applicable Remedial Investigation Work Plan, and must be documented in the field project notebook when they occur.

### 1.2 General Principles

Monitoring well construction and installation generally involves drilling a borehole using conventional drilling equipment, installing commercially available well construction and filter/sealing materials, and development of the well prior to sampling. This POP covers well construction and installation methods only. Borehole drilling and well development methods are covered under POP PPG 005 Surface and Subsurface Soil Sampling Procedures and POP PPG 007 Monitoring Well Development, respectively.

### 1.3 Quality Assurance Planning Considerations

Field personnel should follow specific quality assurance guidelines as outlined in the site-specific QAPP.

The following aspects of monitoring well design and installation procedures depend on project-specific objectives which are addressed in the QAPP and in the Remedial Investigation Work Plan:

- Borehole drilling method and diameter,
- Type of construction materials for well screen, riser, filter pack and seals,
- Diameter of well materials,
- Length of well screen,
- Location, thickness, and composition of annular seals, and
- Well completion and surface protection requirements.

## 2.0 Health and safety considerations

Monitoring well installation may involve chemical hazards associated with materials in the soil or groundwater being investigated; and always involves physical hazards associated with drilling equipment and well construction methods. When wells are to be installed in locations where the aquifer and/or overlying materials may contain chemical hazards, a Health and Safety Plan (HASP) must be prepared and approved by the Health and Safety Officer before field work commences. This plan must be distributed to all field personnel and must be adhered to as field activities are performed.

## 3.0 Interferences

**3.1** Not Applicable

## 4.0 Equipment and materials

**4.1** Well Construction Materials

Well construction materials are usually provided by the drilling subcontractor and most often consist of commercially available flush-threaded well screen and riser pipe constructed of PVC or stainless steel with a minimum 2-inch inside diameter. The length of the screen and the size of the screen slots should be specified in the Remedial Investigation Work Plan.

**4.2** Well Completion Materials

Well completion materials include silica sand, bentonite, cement, protective casings and locks. Completion materials are generally provided by the drilling subcontractor.

**4.3** Other required materials include the following:

- Potable water supply
- Fiberglass or steel measuring tape
- Water level indicator
- Well construction diagrams (A typical well construction diagram is presented as Figure 1)
- Waterproof marker or paint (to label wells)
- Health and Safety supplies
- Equipment decontamination materials
- Field project notebook/pen

## 5.0 Procedures

**5.1** General Preparation

**5.1.1** Borehole Preparation

Standard drilling methods should be used to achieve the desired drilling/well installation depths specified in the Remedial Investigation Work Plan. Soil sampling, if conducted, should be conducted in accordance with POP PPG 005 Surface and Subsurface Soil Sampling Procedures.

The diameter of the borehole must be a minimum of 2 inches greater than the outside diameter of the well screen or riser pipe used to construct the well. This is necessary so that sufficient annular space is available to install filter packs, bentonite seals, and grout seals. Bedrock wells may require reaming after coring in order to provide a large enough borehole diameter for well installation.

Rotary drilling methods requiring bentonite-based drilling fluids, if selected, should be used with caution to drill boreholes that will be used for monitoring well installation. The bentonite mud builds up on the borehole walls as a filter cake and permeates the adjacent formation, potentially reducing the permeability of the material adjacent to the well screen.

**5.1.2** Well Material Decontamination

Although new well materials (well screen and riser pipe) generally arrive at the site boxed and sealed within plastic bags, it is sometimes necessary to decontaminate the materials prior to their use. Well materials should be inspected by the Task Leader upon delivery to check cleanliness. If the well materials appear dirty, or if local or regional regulatory guidance requires decontamination, then well material decontamination should be performed by the drilling subcontractor.

**5.2** Well Construction Procedure

**5.2.1** Depth Measurement

Once the target drilling depth has been reached, the drilling subcontractor will measure the total open depth of the borehole with a weighted, calibrated tape measure. Adjustments of borehole depth can be made at this time by drilling further or installing a small amount of sand filter material to achieve the desired depth. If drilling fluids were used during the drilling process, the borehole should be flushed at this time using potable water. The water table depth may also be checked with a water level indicator if this measurement cannot be obtained with the calibrated tape.

**5.2.2** Centralizers

Centralizers may be used but are not required. Centralizers are especially helpful for deep well installations where it may be difficult to position the well by hand.

Centralizers may not be necessary on shallow water table well installations where the well completion depth is within 25 feet of the ground surface.

**5.2.3** Well Construction

The well screen and riser pipe generally are assembled by hand as they are lowered into the borehole. Before the well screen is inserted into the borehole, the full length of the slotted portion of the well screen as well as the unslotted portion of the top and bottom of the screen should be measured with the measuring tape. These measurements should be recorded on the well construction diagram. The maximum length of well screen (or open borehole in bedrock wells) for monitoring wells is 25 feet. In cases where low-flow sampling is intended in newly installed monitoring wells, the wells should be installed with no more than five feet of screen.

After the above measurement has been taken, the drilling subcontractor may begin assembling the well. As the assembled well is lowered, care should be taken to ensure that it is centered in the hole if centralizers are not used. The well should be temporarily capped before filter sand and other annular materials are installed.

**5.2.4** Filter Sand Installation

The drilling subcontractor should fill the annular space surrounding the screened section of the monitoring well to at least 1 foot above the top of the screen with an appropriately graded, clean silica sand or fine gravel. In general, the filter pack should not extend more than 3 feet above the top of the screen to limit the thickness of the monitoring zone. If coarse filter materials are used, an additional 1-foot thick layer of fine sand should be placed immediately above the filter pack to prevent the infiltration of sealing components (bentonite or grout) into the filter pack. As the filter pack is placed, a weighted tape should be lowered in the annular space to verify the depth to the top of the layer. Depending upon depth, some time may be required for these materials to settle. If necessary, to eliminate possible bridging or creation of voids, placement of the sand pack may require the use of a tremie pipe. Tremie pipe sandpack installations are generally suggested for deep water table wells and for wells which are screened some distance beneath the water table.

**5.2.5** Bentonite Seal Installation

An approximate 1-foot thick layer of slurry seal will be installed by the drilling subcontractor immediately above the well screen filter pack in all monitoring wells. The purpose of the seal is to provide a barrier to vertical flow of water in the annular space between the borehole and the well casing. Bentonite is used because it swells significantly upon contact with water. As an option, powdered bentonite may be mixed with water into a very thick slurry and a tremie pipe used to inject the seal to the desired depth.

**5.2.6** Annular Grout Seal Installation

This grout seal should consist of a bentonite/cement mix with a ratio of bentonite to cement of between 1:5 and 1:20. The grout ratio should be chosen based on site conditions with a higher percentage of bentonite generally used for formations with higher porosity. A mud balance should be used if a specific mud density is required at a particular site. Grout slurry should be pumped into the annular space using a side-discharging tremie pipe located about 2 feet above the sand pack. Side discharge will help preserve the integrity of the sand pack.

In situations where the monitoring well screen straddles the water table, the seal will be in the unsaturated zone. Optionally, seals in this situation may be a cement/bentonite mixture containing up to 10 percent bentonite by weight. This type of mixture shall be tremied to the desired depth in the borehole.

Drill cuttings, even those known not to be contaminated, will not be used as backfill material.

**5.2.7** Well Completion

The drilling subcontractor will cut the top of the well to the desired height and install a vented (if possible), locking cap. The upper portion of the well casing can optionally be drilled to allow venting. Well casings are usually cut to be a certain height above ground surface (typically 2.5 to 3 feet) or are cut to be flush with the ground surface.

**5.2.8** Protective Casing/Concrete Pad Installation

The drilling subcontractor will install a steel guard pipe on the well as a protective casing. The borehole around the guard pipe will be dug out to an approximate 2 to 3-foot radius to a minimum depth of 1 foot at the center and 6 inches at the edges. After installing the protective casing, the excavation will be filled with a concrete/sand mix. The surface of the concrete pad will be sloped so that drainage occurs away from the well. Flush-mount protective casings may not require an extensive concrete pad and should be completed such that they are slightly mounded above the surrounding surface to prevent surface water from running over or ponding on top of the casing. It should be noted, however, that in areas subject to snowfall, flush-mount casings may have to be installed so that they are entirely flush with the ground surface as they may be damaged by snow plows.

Above-ground protective casings should also be vented or should have non-air tight caps. Flush mount installations should not be vented. Installation of additional guard pipes may be necessary around above-ground well completions in traffic areas. Protective casings should be lockable to prevent unauthorized access.

**5.2.9** Well Numbering

The Task Leader will ensure that each well casing is identified with an indelible marker, paint, or stamp. This is particularly important with nested or paired wells to

distinguish between shallow and deep wells. The well should be labeled on both the outside of the protective casing and inside beneath the protective casing lid.

**5.2.10** Measuring Point Identification

The Task Leader will ensure that the measuring point from which water level measurements will be made at each well is marked along the upper edge of the well casing. PVC wells can easily be notched with a pocket knife or saw. Stainless steel wells (or PVC wells) can be marked with a waterproof marker on the outside of the well casing with an arrow pointing to the measuring point location. The measuring point is the point which will require surveying during the well elevation survey task.

**5.2.11** Well Measurements

Upon completion, the following well measurements should be taken and recorded on the well construction diagram (Figure 1):

- Depth to static water level if water level has stabilized,
- Total length of well measured from top-of-well casing,
- Height of well casing above or below ground surface,
- Height of protective casing above ground surface,
- Depth of bottom of protective casing below ground surface (may be estimated).

Well screen filter pack, bentonite seal and annular seal thicknesses and depths should also be recorded on the well construction diagram.

**5.2.12** Disposal of Drilling Wastes

Drill cuttings and other investigation-derived wastes such as drilling mud or well development/purge water must be properly contained and disposed of. Site-specific requirements for collection and removal of these waste materials should be outlined within the Remedial Investigation Work Plan. Containment of these materials should be performed by the drilling subcontractor.

**5.2.13** Well Development

After installation of a well and prior to use of the well for water-level measurements or collection of water quality samples, development of the well shall be undertaken in accordance with POP PPG 007 Monitoring Well Development. Well development will be performed by the drilling subcontractor.

**5.2.14** Well Elevation Survey

At the completion of the well installation program, all monitoring wells are to be surveyed by a surveying subcontractor in accordance with NJDEP requirements.

**5.2.15** Double Casing

In boreholes where a shallow water-bearing zone is encountered above a deeper water bearing zone, casing will be installed to prevent downward migration between the water-bearing zones in accordance with N.J.A.C. 7.9D. The casing will be installed to a sufficient depth to prevent migration between the water-bearing zones, and the annular space between the casing and borehole, as well as the annular space between water-bearing zones, will be grouted. The grout will be allowed to set for a minimum of 24 hours prior to further advancement of the borehole.

In accordance with the NJDEP FSPM, installation of well couplets (e.g., shallow and deep) and well triplets (e.g., shallow, intermediate and deep) will be installed in separate boreholes since grout is less likely to invade well intakes (screens) if the wells are installed in separate boreholes. Care will be taken to assure that any confining unit between aquifer zones is not breached without providing adequate protection of underlying/overlying aquifers.

In accordance with Subchapter 2 (Requirements and Procedures for the Construction, Installation, Operation and Maintenance of Wells) NJAC 7:9D-2.1(a), *"monitoring wells, air sparging wells, soil vapor extraction wells, recovery wells, and wells or well points installed for environmental remediation projects"* are considered Category 3 wells for the purposes of establishing general and specific well construction standards[1].

In accordance with NJAC 7:9D-2.4, the following specific requirements also apply to Category 3 wells in unconsolidated aquifers where a confining layer(s) exist shall be constructed in accordance with the following:

1. The screened interval or the filter pack shall not extend across the interface of a confining layer.

2. Monitoring wells will be constructed in accordance with Figure 6.14 on Page 173 of 188 of the August 2005 NJDEP Field Sampling Procedures Manual (see below). The outer casing shall be driven to a minimum of one foot below the drilled borehole.

[1] The requirements in NJAC 7:9D-2.1(b)1, requiring a minimum of 20 feet of outer-most well casing into the confining layer or to the base of the confining layer is intended for water supply wells and in areas where there is salt water intrusion where double casing is needed to protect the water supply.

**Field Sampling Procedures Manual**
Chapter 6G – Page 173 of 188

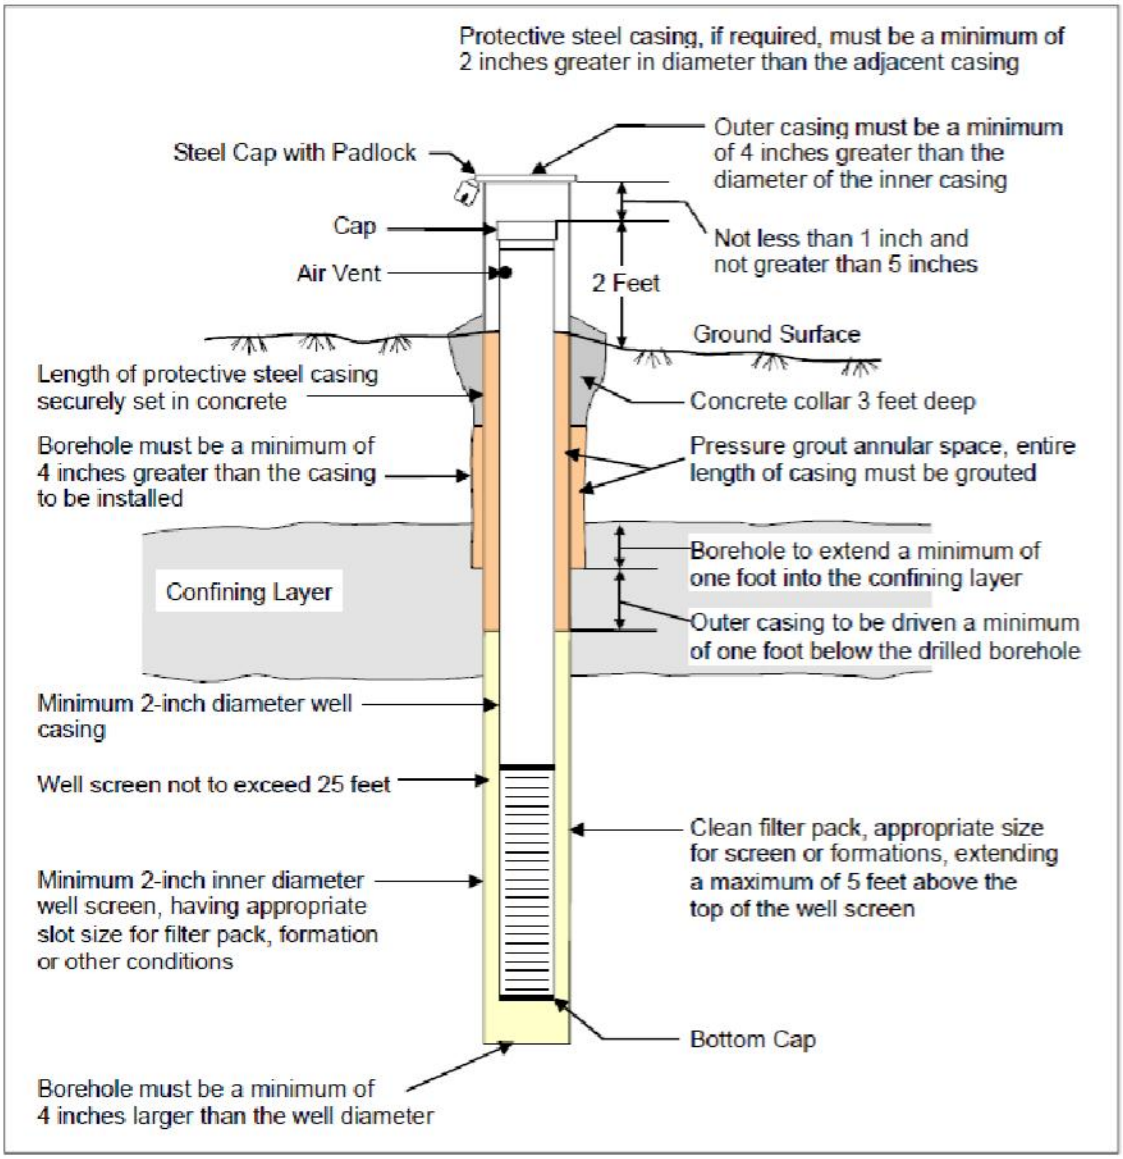

Figure 6.14 Confined Unconsolidated Aquifer Well

## 6.0 Quality assurance / quality control

Certain quality control measures should be taken to ensure proper well completion.

- The borehole will be checked for total open depth, and extended by further drilling or shortened by backfilling, if necessary, before any well construction materials are placed.
- Water level and non-aqueous phase liquid (NAPL) presence will be checked during well installation to ensure that the positions of well screen, sand pack, and seal, relative to water level, conform to project requirements.
- The depth to the top of each layer of packing (i.e., sand, bentonite, grout, etc.) will be verified and adjusted if necessary to conform to project requirements before the next layer is placed.
- If water or other drilling fluids have been introduced into the boring during drilling or well installation, samples of these fluids may be required for analysis of chemical constituents of interest at the site.

## 7.0 Data and records management

All well construction data will be recorded on the Monitoring Well Construction Detail form. A typical Monitoring Well Construction Detail form is presented as Figure 1. All wells will be referenced onto the appropriate site map. A field notebook and/or boring log will be used as additional means of recording data. In no case will the notebook or boring log take the place of the well construction diagram.

## 8.0 Personnel qualifications and training

Well construction and installation requires a moderate degree of training and experience as numerous drilling situations may occur which will require field decisions to be made. Inexperienced personnel will be supervised until they are capable of working on their own. Experienced drillers will be utilized, as they are also of great assistance with problem resolution in the field. Field personnel should be health and safety certified as specified by OSHA (29 CFR 1910.120(e)(3)(i)) to work on sites where hazardous waste materials are considered to be present.

### **8.1** Project Manager

It is the responsibility of the Project Manager to ensure that each project involving monitoring well installation is properly planned and executed. The project manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources, and guidance necessary to perform the measurements in accordance with this POP and the project plan.

**8.2** Task Leader

The Task Leader for drilling activities will be a geologist or hydrogeologist. It is the responsibility of the Task Leader to directly oversee the construction and installation of the monitoring well by the drilling subcontractor to ensure that the well-installation specifications defined in the Remedial Investigation Work Plan are adhered to, and that all pertinent data are recorded on the appropriate forms.

**8.3** Drilling Subcontractor

The drilling subcontractor is required to obtain the necessary permits and must be licensed in accordance with N.J.A.C. 7:9D. It is the responsibility of the drilling subcontractor to provide the necessary equipment for well construction and installation. Well construction materials should be consistent with project requirements. The drilling contractor will be licensed in accordance with applicable State regulations, and will be responsible for obtaining all necessary permits.

**8.4** Surveying Subcontractor

It is the responsibility of the surveying subcontractor to provide one or more of the following well measurements as specified in the Remedial Investigation Work Plan: ground surface elevation, horizontal well coordinates, top of well casing elevation (i.e., top-of-casing, or measuring point elevation), and/or top of protective casing elevation.

Project Operating Procedure

# Monitoring Well Development

## 1.0 Scope and Applicability

### 1.1 Purpose and Applicability

This POP describes the methods used for developing newly installed monitoring wells and/or existing wells which may require redevelopment/rehabilitation. This POP is applicable to monitoring wells and/or small diameter recovery wells and piezometers.

Monitoring well development and/or redevelopment is necessary for several reasons:

- To improve/restore hydraulic conductivity of the surrounding formations as they have likely been disturbed during the drilling process, or may have become partially plugged with silt,
- To remove drilling fluids (water, mud), when used, from the borehole and surrounding formations, and
- To remove residual fines from well filter materials and reduce turbidity of groundwater, therefore, reducing the chance of chemical alteration of groundwater samples caused by suspended sediments.

Respective state or federal agency (regional offices) regulations may require specific types of equipment for use or variations in the indicated method of well development. Deviations from this POP to accommodate other regulatory requirements should be reviewed in advance of the field program, should be explained in the Work Plan or Quality Assurance Project Plan (QAPP), and must be documented in the field logbook when they occur.

### 1.2 General Principles

Well development generally involves withdrawal of an un-specified volume of water from a well using a pump, surge block or other suitable method such that, when completed effectively, the well is in good or restored hydraulic connection with the surrounding water bearing unit and is suitable for obtaining representative groundwater samples or for other testing purposes.

## 2.0 Health and Safety Considerations

Monitoring well development may involve chemical hazards associated with materials in the soil or aquifer being characterized and may involve physical hazards associated with use of well development equipment. When wells are to be installed and developed on hazardous waste investigation sites, a Health and Safety Plan must be prepared and approved by the Health and Safety Officer before field work commences. This plan must be approved by the project Health and Safety Officer before work commences, must be distributed to all field project personnel, and must be adhered to as field activities are performed.

## 3.0 Interferences

Well development performed with inappropriate techniques or improper procedures may lead to groundwater monitoring data that is not representative of the formation. Careful consideration should be given to the monitoring well development method selected, and the procedures should be followed as presented in this POP.

Monitoring well development will be conducted a minimum of 8 hours after completion of the well construction to allow the grout to set.

## 4.0 Equipment and Materials

Well development can be performed using a variety of methods and equipment. The specific method chosen for development of any given well is governed by the purpose of the well, well diameter and materials, depth, accessibility, geologic conditions, static water level in the well, and type of contaminants present, if any.

The following list of equipment, each with their own particular application, may be used to develop and/or purge monitoring wells.

### **4.1** Bailer Purging

A bailer is used to purge silt-laden water from wells after using other devices such as a surge block. In some situations, the bailer can be used to develop a well by bailing and surging, often accompanied with pumping. A bailer should be used for purging in situations where the depth to static water is greater than 25 feet and/or where insufficient hydraulic head is available for use of other development methods.

### **4.2** Surge Block Development

Surge blocks are commercially available for use with Waterra™-type pumping systems or may be manufactured using a rubber or teflon "plunger" attached to a rod or pipe of sufficient length to reach the bottom of the well. Well drillers usually can provide surge blocks if requested. A recommended design is shown in Figure 1.

### **4.3** Pump Development

A pump is often necessary to remove large quantities of silt-laden ground water from a well after using the surge block. In some situations, the pump alone can be used to develop the well and remove the fines by overpumping. Since the purpose of well development is to remove suspended solids from a well and surrounding filter pack, the pump must be capable of moving some solids without damage. The preferred pump is a submersible pump which can be used in both shallow and deep ground water situations. A centrifugal pump may be used in shallow wells but will work only where the depth to static ground water is less than approximately 25 feet. Pumping may not be successful in low-yielding aquifer materials or in wells with insufficient hydraulic head.

**4.4** Compressed Gas Development

Compressed gas, generally nitrogen from a tank or compressed air through a compressor, can be used to both surge and develop a monitoring well. The method works by injection of compressed gas at the bottom of the water column, driving sediment-laden water to the surface. Compressed gas can also be used for "jetting" - a process by which the gas is directed at the slots in the well screen to cause turbulence (thereby disturbing fine materials in the adjacent filter pack). Compressed gas is not limited by any depth range.

Since the compressed gas will be used to "lift" water from the monitoring well, provisions must be made for controlling the discharge from contaminated wells. This is generally accomplished by attaching a "tee" discharge to the top of the casing and providing drums to contain the discharged water. Gas-lifting should never be done in contaminated wells without providing a means to control discharge.

**4.5** Other Required Materials:

- Well development records (Figure 2)
- Health and Safety equipment
- Equipment decontamination materials
- Water level indicator
- Water quality instrumentation: turbidity meter, pH, temperature, specific conductance meters, as required
- Field logbook/pen

## 5.0 Procedures

**5.1** General Preparation

**5.1.1** Well Records Review: Well completion diagrams should be reviewed to determine well construction characteristics. Formation characteristics should also be determined from review of available boring logs.

**5.1.2** Site Preparation: Well development, similar to groundwater sampling, should be conducted in as clean an environment as possible. This usually requires, at a minimum, placing sheet plastic on the ground to provide a clean working area for development equipment.

**5.1.3** Monitoring well development will occur a minimum of 8 hours after completion of monitoring well construction, to allow the grout to set.

**5.1.4** IDW Containment: Provisions should be in place for collection and management of investigation-derived wastes (IDW), specifically well development water and miscellaneous expendable materials generated during the development process. The collection of IDW in drums or tanks may be required depending on project-specific requirements.

**5.1.5** Water Level/Well Depth Measurement: The water level and well depth should be measured with a water level indicator and written on the well development record. This information is used to calculate the volume of standing water (i.e., the well volume) within the well.

**5.1.6** Equipment Decontamination: All down-well equipment should be decontaminated prior to use in accordance with the NJDEP Field Sampling Procedures Manual. Refer to POP PPG 014, Decontamination of Field Equipment.

**5.1.7** Removal of Drilling Fluids: Drilling fluids such as mud or water, if used during the drilling and well installation process, should be removed during the well development procedure. It is recommended that a minimum of 1.5 times the volume of added fluid be removed from the well during development. Drilling muds should initially have been flushed from the drilling casing during the well installation procedure with water added during the flushing process. If the quantity of added fluid is not known or could not be reasonably estimated, removal of a minimum of 10 well volumes of water is recommended during the development procedure.

**5.2** Development Procedures

**5.2.1** Development Method Selection

The construction details of each well shall be used to define the most suitable method of well development. Some consideration should be given to the potential degree of contamination in each well as this will impact IDW containment requirements.

The criteria for selecting a well development method include well diameter, total well depth, static water depth, screen length, the likelihood and level of contamination, and characteristics of the geologic formation adjacent to the screened interval.

The limitations, if any, of a specific procedure are discussed within each of the following procedures.

**5.2.2** General Water Quality Measurements

Measure and record water temperature, pH, specific conductance, and turbidity periodically during development using the available water quality instruments. These measurements will aid in determining whether well development is proceeding efficiently, will assist in identifying when well development is complete, will determine whether the development process is effective or not with any given well and, potentially, may identify well construction irregularities (i.e., grout in well, poor well screen slot-size selection). Water quality parameters should be checked a minimum of 3 to 5 times during the development process.

**5.2.3** Bailer Procedure

- As stated previously, bailers shall preferably not be used for well development but may be used in combination with a surge block to remove silt-laden water from the well.
- When using a bailer to purge well water; select the appropriate bailer, then tie a length of bailer cord onto the end of it.

- Lower the bailer into the screened interval of the monitoring well. Silt, if present, will generally accumulate within the lower portions of the well screen.
- The bailer may be raised and lowered repeatedly in the screened interval to further simulate the action of a surge block and pull silt through the well screen.
- Remove the bailer from the well and empty it into the appropriate storage container.
- Continue surging/bailing the well until sediment-free water is obtained. If moderate to heavy siltation is still present, the surge block procedure should be repeated and followed again with bailing.
- Check water quality parameters periodically.

**5.2.4** Surge Block Procedure

- A surge block effectively develops most monitoring wells. This device first forces water within the well through the well screen and out into the formation, and then pulls water back through the screen into the well along with fine soil particles. Surge blocks may be manufactured to meet the design criteria shown in the example (Figure 1) or may be purchased as an adaptor to fit commercially available well purging systems such as the Waterra system.
- Insert the surge block into the well and lower it slowly to the level of static water. Start the surge action slowly and gently above the well screen using the water column to transmit the surge action to the screened interval. A slow initial surging, using plunger strokes of approximately 3 feet, will allow material which is blocking the screen to separate and become suspended.
- After 5 to 10 plunger strokes, remove the surge block and purge the well using a pump or bailer. The returned water should be heavily laden with suspended silt and clay particles. Discharge the purged water into the appropriate storage container.
- Repeat the process. As development continues, slowly increase the depth of surging to the bottom of the well screen. For monitoring wells with long screens (greater than 10 feet) surging should be undertaken along the entire screen length in short intervals (2 to 3 feet) at a time. Continue this cycle of surging and purging until the water yielded by the well is free of visible suspended material.
- Check water quality parameters periodically.

**5.2.5** Pump Procedure

- Well development using only a pump is most effective in monitoring wells that will yield water continuously. Theoretically, pumping will increase the hydraulic gradient and velocity of groundwater near the well by drawing the water level down. The increased velocity will move residual fine soil particles into the well and clear the well screen of this material. Effective development cannot be accomplished if the pump has to be shut off to allow the well to recharge.
- When using a submersible pump or surface pump, set the intake of the pump or intake line in the center of the screened interval of the monitoring well.
- Pump a minimum of three well volumes of water from the well and raise and lower the pump line through the screened interval to remove any silt/laden water.
- Continue pumping water from the well until sediment-free water is obtained. This method may be combined with the manual surge block method if well yield is not rapid enough to extract silt from the surrounding formations.
- Check water quality parameters periodically.

**5.2.6** Compressed Gas Procedure

- Although the equipment used to develop a well using this method is more difficult to obtain and use, well development using compressed gas is considered to be a very effective method. This method is also not limited by well depth, well diameter, or depth to static water. Caution must be exercised, however, in highly permeable formations not to inject gas into the formation. Drilling subcontractors will often provide the necessary materials as well as perform this method , if requested. When using a compressor, an oil-less compressor should be used, or an oil trap/filter should be placed on the air discharge line which enters the well.
- Lower the gas line into the well, setting it near the bottom of the screened interval. Install the discharge control equipment (i.e., tee fitting) at the well head.
- Set the gas flow rate to allow continuous discharge of water from the well.
- At intervals during gas-lifting, especially when the discharge begins to contain less suspended material , shut off the air flow and allow the water in the well to backflush through the screened interval to disturb any bridging that may have occurred. Re-establish the gas flow when the water level in the well has returned to the pre-development level.
- Continue gas-lifting and/or jetting until the discharged water is free from suspended material.
- Check water quality parameters periodically.

**5.2.7** Special Considerations for Wells in Low-Permeability Formations

Wells installed in low-permeability formations may be difficult to develop due to the slow rate of recharge into the well resulting in the well purging dry before proper well development can be achieved. When developing wells under these circumstances, the addition of potable water to the well during development to maintain a sufficient well volume should be considered. Approval from all appropriate regulatory agencies, including permitting requirements, must be obtained prior to implementing this procedure modification. If implemented, the following must be followed:

- The well development record must document that the addition of potable water is being used to aid in the development of the well and the justification for doing so.
- The volume of water added to the well must be documented.

**5.2.8** A minimum of 1.5 times the volume of water added to the well must be purged from the well. The total volume of water purged should be recorded on the well development record to document that this has been performed.

## 6.0 Quality Assurance / Quality Control

Field project personnel should follow specific quality assurance guidelines as outlined in the QAPP. The plan should indicate the preferred method of well development at a particular site based on project objectives, aquifer conditions, and agency requirements. Specific well performance criteria such as low turbidity values to be achieved following well development should also be specified as well as any requirements for collection/containerization and disposal of well development water.

A well has been successfully developed when one or more of the following criteria are met:

- The sediment load in the well has been eliminated or greatly reduced. Regulatory requirements may be in place which state that water turbidity values ranging from 5 to 50 NTU must be achieved at the end of the development procedure. Use of a turbidity meter is required during the well development procedure to measure water turbidity if meeting a specific turbidity value is required by the regulations. Attaining low turbidity values in fine-grained formations may be difficult to achieve.
- Permeability tests yield repeatable hydraulic conductivity values.

## 7.0 Data and Records Management

The Monitoring Well Development Record (Figure 2) will be completed by the geologist or hydrogeologist conducting the development. In addition, a field logbook should be maintained documenting any problems or unusual conditions which may have occurred during the development process.

Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records. Records associated with the activities described in this POP will be maintained according to the document management policy for the project.

## 8.0 Personnel Qualifications and Training

Well development procedures vary in complexity. It is recommended that initial development attempts be supervised by more experienced personnel. Field personnel should be health and safety certified as specified by OSHA (29 CFR 1910.120(e)(3)(i)) to work on sites where hazardous waste materials are considered to be present. For wells that are located in New Jersey, all well development or redevelopment work shall be performed by a licensed well driller of the proper class in accordance with N.J.A.C. 7:9D-2.11(b).

**8.1** Responsibilities

**8.1.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

**8.1.2** The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

## 10.0 Revision History

| Revision | Date | Changes |
|---|---|---|
| 0 | June 2010 | Original POP |

## APPENDIX: DEFINITIONS

Bridging: A condition within the filter pack outside the well screen whereby the smaller particles are wedged together in a manner that causes blockage of pore spaces.

Hydraulic Conductivity: A characteristic property of aquifer materials which describes the permeability of the material with respect to flow of water.

Hydraulic Connection: A properly installed and developed monitoring well should have good hydraulic connection with the aquifer. The well screen and filter material should not provide any restriction to the flow of water from the aquifer into the well.

Permeability Test: Used to determine the hydraulic conductivity of the aquifer formation near a well screen. Generally conducted by displacing the water level in a well and monitoring the rate of recovery of the water level as it returns to equilibrium. Various methods of analysis are available to calculate the hydraulic conductivity from these data.

Static Water Level: The water level in a well that represents an equilibrium or stabilized condition, usually with respect to atmospheric conditions in the case of monitoring wells.

Well Surging: That process of moving water in and out of a well screen to remove fine sand, silt and clay size particles from the adjacent formation.

Well Purging: The process of removing standing water from a well to allow surrounding formation water to enter the well.

Well Screen: That portion of the well casing material that is perforated in some manner so as to provide a hydraulic connection to the aquifer. The perforated, or slotted, portion of a well is also known as the screened interval.

Attachment 1: Monitoring Well Sampling Worksheet

Project Operating Procedure

# Low Stress Groundwater Sampling Procedures

## 1.0 Project Scope and applicability

This procedure is for the collection of groundwater samples that are indicative of mobile organic and inorganic loads at ambient flow conditions (both the dissolved fraction and the fraction associated with the mobile particulates). The procedure emphasizes the need to minimize stress on the aquifer by using low pumping rates (below 1 liter per minute) and allowing minimal or no drawdown in order to collect samples with minimal alterations to water chemistry. The procedure also reduces the volume of purge water generated, thereby reducing disposal costs. A minimum purge volume, based on well screen length and whether the water level is below the top of the screen, is specified so that samples will be representative of the conditions of the groundwater flowing through the well screen.

The procedure is suited for monitoring wells that have a screen, or open interval, of 10 feet or less but is also applicable to wells with longer well screens. The monitoring wells must be sufficiently wide to simultaneously accept a submersible pump or intake tubing from a peristaltic pump, and the probe from an electronic water level indicator. The screened or open interval must be positioned to intercept the existing contaminant plume, and the monitoring well must be properly constructed, developed, and maintained. This procedure does not address the collection of samples from wells containing light or dense non-aqueous phase liquids (LNAPL/DNAPL).

## 2.0 Health and safety considerations

All calibration, maintenance and servicing of the instrumentation should be performed in a safe area, away from hazardous locations.

Refer to the Site Specific Health and Safety Plan for additional Health and Safety issues.

## 3.0 Interferences

Contaminants that are known to adsorb to particulates, such as metals, PCBs, etc., will be impacted by elevated turbidity (i.e., >25 NTU). If the turbidity stabilizes above 25 NTU, samples for metals, PCBs, and other analyses that may be impacted by contaminants adsorbed to suspended particulates will be filtered using an in-line 0.45 micron filter prior to sample collection. However, groundwater samples to be used in Risk Assessment should not be filtered unless an unfiltered sample will also be submitted for the same analysis. Decisions to sample when turbidity remains above 10 NTU shall be made in consideration of the analyses that will be performed and the project objectives.

ORP is a difficult parameter to measure in the field because the length of time which is necessary for the probe to obtain an accurate measurement is too long to be conducive to use during low-stress monitoring. Consequently, ORP readings may continue to increase or decrease slowly over the purging period.

Gas bubbles present in discharge tubing during purging and sampling are a problem: Their presence indicates off-gassing from groundwater or poor purging connections in the airline or groundwater tubing. Sunlight can exacerbate this problem when low pumping rates are used. Check connections at the surface. If bubbles persist, check connections at the pump. Erect an umbrella to shade and insulate the transparent flow-through cell and tubing to prevent exposure to direct sunlight. During purging and sampling, observe the flow of groundwater in the sample tubing and keep the tubing filled with groundwater, removing all air pockets and bubbles, to the extent possible. Gas bubbles may be reduced by increasing flow, if possible, and keeping tubing and the transparent flow-through cells shaded. Monitor the flow-through cell for trapped gases which can impact the readings. Placing the flow-through cell at a 45 degree angle with the port side facing upwards can help remove air bubbles from the flow-through cell (see Figure 1).

Thermal currents in the monitoring well may cause vertical mixing of water in the well bore. When the air temperature is colder than the groundwater temperature, it can cool the top of the water column. Colder water which is denser than warm water sinks to the bottom of the well and the warmer water at the bottom of the well rises, setting up a convection cell. "During low-flow sampling, the pumped water may be a mixture of convecting water from within the well casing and aquifer water moving inward through the screen. This mixing of water during low-flow sampling can substantially increase equilibration times, can cause false stabilization of indicator parameters, can give false indication of redox state, and can provide biological data that are not representative of the aquifer conditions" (Vroblesky 2007).

Pump tubing lengths above the top of well casing should be kept as short as possible to minimize heating the groundwater in the tubing by exposure to sun light and ambient air temperatures. Heating may cause the groundwater to degas, which is unacceptable for the collection of samples for VOC and dissolved gases analyses.

## 4.0 Equipment and materials

**4.1** Submersible pumps, bladder pumps, positive displacement pumps, or peristaltic pump

In selecting the appropriate pump, the sampler must consider the head pressure the pump must overcome (the distance between the water level and the highest point over which the purge water must be raised), the depth to the desired sampling interval, the inner diameter of the inner well casing, the analyses to be performed, and the associated logistics (power source, well accessibility). The pump selected must have sufficient lift capacity for the head pressure anticipated. Peristaltic pumps are effective up to a depth to water of approximately 27 feet (note that this must be measured from the highest point that the water must be raised, such as the top of the outer casing). The pump must be sufficiently small to fit into the well along with the water level indicator. The associated pressure lines, power lines, and purge and intake lines must be sufficiently long to reach to the intended sampling interval. As per EPA guidance, peristaltic pumps or other pumps that use suction shall be avoided for sampling volatile compounds, gases (methane, ethane, ethene), and other parameters that may be impacted by degassing and pH modification. For these analyses, peristaltic pumps must not be used when project decisions hinge on detection of low concentrations of VOCs. ***Peristaltic pumps will not***

***be used for collection of any samples that include hexavalent chromium or VOCs as part of the analytical suite.***

### **4.2** Bladder Pump

The bladder pump system contains the following components: a pressurized cylinder of inert gas (typically nitrogen), a pump controller, air intake and discharge lines, and bladder pumps. Dedicated bladder pumps installed at some sites, may also have an extension designed to lower the pump intake below the level of the pump. The controller regulates total flow of nitrogen from the pressurized nitrogen cylinder to the pump assembly located in the well. AECOM typically samples one well per nitrogen cylinder. Note that if the bladder pumps are placed at the same depth in each well, multiple wells may be sampled simultaneously with one nitrogen cylinder. In this case, a three-way cross splitter with quick-connect air line fittings is attached to the tubing connected to the nitrogen cylinder. Up to three controllers can then be connected to the nitrogen cylinder. If nitrogen cylinders are not available, air compressors may be used to power the bladder pumps.

The tubing bundle connected to the pump has three components: an air line with fittings to the pump and the controller, a sample line, and a Teflon-coated support cable. The sample line, through which the purge water is removed, should be composed entirely of Teflon. In locations where dedicated bladder pumps are installed, the tubing bundle and support cable may be connected to a well plate recessed below the locking cap.

### **4.3** Peristaltic Pump

Peristaltic pumps are not submerged in the well, but remain outside of the well and function by pulling water to the surface. Use is therefore not approved for collection of samples requiring analysis for volatile organic compounds, gases, or other analyses that may be impacted by changes in pressure or pH, including hexavalent chromium. A peristaltic pump has a rotating pump head with stepless variable speed that compresses a short stretch of flexible (Pharmed) silicone tubing to pull water up from the well using mechanical peristalsis. The sample water does not come into direct contact with the pump. Teflon tubing is connected to either end of the silicone tubing. The pumps typically used by AECOM, the GeoPump or GeoPump II by GeoTech, operate off an external 12 V battery or 120 V AC power source. Commercially available “JumpStart” 12 volt batteries are typically preferred since electrical hookup is typically not available; since they are safe, easy to carry, and easy to recharge; and since the potential contamination issues associated with use of a generator are avoided.

### **4.4** Submersible Pump

Submersible pumps used are typically electrical centrifugal pumps. A centrifugal submersible pump consists of impellers or vanes that are spun or rotated by a sealed electric motor. The spinning of the impellers that causes water to be accelerated outward and then upward into the pump's discharge line. The higher the pumping rate, the greater the potential for sample alteration by sample agitation, increased turbulence and pressure changes in the sample. However, maintaining flow in the low-flow range (less than 1,000 mL per minute) is considered acceptable. A centrifugal submersible pump is usually suspended in a monitoring well by a support cable. Electrical submersible pumps typically used by AECOM are the Grundfos Redi-Flo 2, or similar. These are centrifugal pumps constructed of stainless steel and Teflon, and the motors are cooled and lubricated with water rather than with

hydrocarbon-based coolants and lubricants that could contaminate groundwater samples. The pumps can achieve flow rates as low as 100 mL per minute. The pumps require a 115 or 230 volt electrical supply, therefore a generator is typically required. Pumps are available for wells 2" in diameter or larger.

**4.5** Tubing suited to the pumps and flow-through cells to be used

Teflon or Teflon-lined polyethylene tubing are preferred for all parameters. Stainless steel tubing may be used for sampling organics, but is not recommended for inorganics. PVC, polypropylene or polyethylene may be used for sampling inorganics. Pharmaceutical-grade (e.g. Pharmed) silicon tubing shall be used around the rotor head of the peristaltic pump, and if necessary as a connecting tubing to the flow-through cells. Inner tubing diameter should be kept to the smallest size possible to reduce the generation of air pockets during low flow. Tubing typically used with the peristaltic pumps is Teflon of 1/4-inch outside diameter, and 3/16-inch outside diameter.

**4.6** Electronic water level indicator: Solinst Model 101 or similar

Inner casing diameter and pump diameter should be considered in selecting a water level indicator that will fit into the well with the pump. A smaller diameter probe may be required for smaller wells.

**4.7** High-Density Polyethylene (HDPE) Y connectors and tubing clamps

These allow for removal of an aliquot of purge water prior to the flow-through cell for turbidity analysis.

**4.8** Flow controllers and compressed inert gases for submersible bladder pumps

QED Model MP-10 Flow controller and nitrogen gas are typically used unless nitrogen is an analyte of interest. Portable air compressors may be used in place of compressed gas (e.g., QED Well Wizard).

**4.9** Power source

Marine battery, battery pack, compressed gas and flow-controller, or generator and heavy duty extension cords depending on pump

**4.9.1** Bladder Pumps

For bladder pump operation, the cylinders of inert compressed gas or portable air compressors function with the flow controller as the power source, although the flow controller does require batteries.

**4.9.2** Peristaltic Pumps

The peristaltic pumps typically used by AECOM require an external 12 volt battery or 120 volt AC power source. Commercially available 12 volt batteries designed for jump-starting a car battery (“JumpStart” or similar) are preferred since electrical hookup is typically not available; since they are safe, easy to carry, and easily rechargeable; and since the potential contamination issues associated with use of a generator are avoided.

**4.9.3** Submersible Pumps

An external power source is required. If use of a generator is required, precautions must be taken to avoid cross-contamination when handling fuel and when locating the generator to prevent contamination of the samples and sampling equipment by fumes and exhaust.

**4.10** Water Quality Meter with Transparent Flow-Through Cell

YSI 6820 Water Quality Meter and transparent Flow-through cell with 610DM data manager, or similar model

**4.11** Turbidity Meter

LaMotte 2020 turbidity meter, or similar model

**4.12** Other Equipment

- Photoionization Detector (PID)
- Tarp, umbrellas, or other means to shade the tubing, flow-through cells, and water quality meters from direct sunlight
- Graduated cylinders
- Watch with seconds hand
- Graduated plastic purge buckets or carboys
- Well information consisting of well casing diameter, depth to bottom, depth to top and bottom of screened interval, desired depth for sample collection, depth of pump intake (if dedicated pumps are in place) and results of synoptic water level measurements and LNAPL/DNAPL survey.

## 5.0 Procedures

This section includes the procedures for performing field activities that should be conducted prior to sampling, procedures for purging the wells using the different pumps, and the sampling and post-sampling procedures (which are the same for the different pump types).

**5.1** Pre-Sampling Field Activities

Prior to beginning sampling activities in any wells, all required synoptic water level measurements and well soundings should be completed in accordance with the POP for Water Level Measurements.

Wells should be inspected for the presence of DNAPL or LNAPL. Wells with NAPL cannot be sampled using low-flow techniques, and must be sampled with an alternative sampling method, such as bailing.

All non-dedicated down-well measuring devices will be thoroughly decontaminated before sampling and between monitoring locations.

Sampling should begin at the monitoring well likely to have the lowest levels of contamination, generally upgradient or farthest from the site or suspected source, and proceed such that the most contaminated wells are sampled last.

Record the monitoring location identification number. Check the monitoring location for damage or evidence of tampering, and record observations.

Place polyethylene sheeting on the ground and assemble all necessary sampling equipment on top of it. This helps to prevent contamination of the sampling equipment by the soil, reduces wear on the sampling equipment due to dirt, and reduces the likelihood that contaminated purge water will spill into the surface soil.

Unlock the protective outer casing (if present) and remove the outer well cap.

Remove the inner well cap, and measure the well headspace and breathing zone for total organic vapors. If it is windy, stand upwind of the well to conduct measurements. For well headspace, place the intake of the PID approximately two inches below the plane formed by the top of the inner casing. Measure the total volatile organic concentrations in the breathing zone. Record both readings. Use the breathing zone concentrations to determine appropriate health and safety measures in accordance with the site-specific health and safety plan.

**5.2** Purging the Wells

The procedure for sampling with bladder pumps is as follows:

Connect all the lines to the pump. If a dedicated bladder pump is in place, the tubing will already be connected to the pump and is likely connected to the well plate.

Carefully lower the pump to the desired sampling depth using the suspension cable. Take care to minimize disturbance and contact with the well walls which could knock rust or other deposits into the standing water. Secure the pump using the suspension cable.

Connect the pump power cable to the power source. Bladder pumps are driven by compressed gas or air through a controller. The controller typically requires batteries. Connect the regulator, pressurized inert gas cylinder or air compressor, flow controller, and pump. If using compressed gas, use a crescent wrench to attach the regulator to the pressurized nitrogen cylinder. Connect the air line from the regulator to the intake valve of the flow controller. Connect the air line from the outflow valve of the flow controller to the airline to the dedicated bladder pump.

Carefully install a flow-through cell on the sonde. Avoid touching the oxygen probe. Connect a purge water discharge line to the flow-through cell of the water quality meter.

Connect the purge water discharge line from the well to the water quality meter using a HDPE Y connector and pinch valve so that an aliquot of purge water can be obtained before the flow-through cell for turbidity measurements. Connect the discharge tubing from the well to the HDPE Y connector fitting using a short piece of silicone tubing. Attach a piece of silicone tubing to one end of the fitting and close it with a pinch value or check valve unit. Samples for turbidity measurements will be collected by opening this pinch valve. Connect the other end of the Y connector fitting to the lower of the two openings in the flow-through cell using silicon tubing and short pieces of Teflon tubing. Connect a piece of Teflon tubing to the out flow of the flow-through cell to the purge bucket. Use a short piece of silicon tubing at the cell. Be sure to use a piece of Teflon tubing sufficiently long to allow purge water to flow easily into the purge bucket.

Mount the sonde and flow-through cell assembly at a 45 degree angle to allow air bubbles to escape from the cell, and position the sonde such that any groundwater spills will be directed away from the sample.

Slowly open the valve on the regulator attached to the nitrogen cylinder until the pressure gauge reads approximately 60 pounds per square inch (PSI). Adjust the regulator on the flow controller to approximately 10 - 20 PSI.

Re-measure the static water level.

Determine the minimum purge volume required for the well. Samples should only be collected after the required volume has been removed from the well. For screen lengths of ten feet or less, a minimum volume of one saturated screen length plus drawdown volume must be removed. For screen lengths greater than ten feet, a minimum purge volume of three saturated screen lengths plus drawdown volume must be removed.

If the depth to water is less than the depth to the top of the screen, the screen is fully saturated and the minimum purge volume is one saturated screen length plus drawdown volume for screens of ten feet of less or three saturated screen lengths plus drawdown volume for screens greater than ten feet.

If the depth to water is greater than the depth to the top of the screen, calculate the well volume. Subtract the difference between the depth to water and the depth to the top of the screen from the well screen length to obtain the saturated well screen length. Round the saturated well screen length up to the nearest foot, and calculate the well volume using the volume per foot of screen length. Multiply the saturated well screen volume by three if the well screen length is greater than 10 feet.

Record the saturated well screen length and the saturated well screen volume on the sampling worksheet.

Start the flow controller and begin purging at the slowest rate possible.

- Note the purge start time.
- Collect all purge water in a bucket or carboy.

- Slowly increase the pressure at the controlled until discharge begins. The bladder pump controller should be set to allow for adequate recharge such that a maximum flow rate with no drawdown is achieved (generally 100-1,000 mL/min) and a smooth, even discharge flow is achieved. Refer to the historical flow controller settings for the well to select the starting controller pressure and intake and discharge intervals.
- Measure the flow rate using a graduated cylinder and time piece and monitor the water level and pumping rate.

Once drawdown has stopped and an acceptable flow rate established, begin monitoring indicator parameters and continue monitoring flow rate and water level.

- Record reading every three to five minutes, or as appropriate for the flow rate and flow-through cell volume. Use the water quality meter to monitor the following: temperature, pH, specific conductance, DO, and ORP. Use a turbidity meter to monitor turbidity.
- In the event that the well has extremely low recharge such that the lowest purge rate possible (100 mL/min or more, if equipment cannot effectively purge that slowly) continues to dewater the well, do not allow a water level that was above the top of the screen to drop below it, do not allow a water level already below the top of the screen to drop further, do not allow the water level to drop below the pump intake, and do not pump the well dry under any circumstances. Notify the field team leader of the situation. If all efforts to avoid dewatering the well have failed, a decision may be made to allow the well to recharge to a level sufficient to allow for collection of the necessary sample volume and to sample the well immediately. Record detailed notes concerning the sampling of the well.
- Stop purging when all parameters have stabilized. Parameters are considered to have stabilized if, over three consecutive readings, the following criteria are met:
    - pH ± 0.1 unit
    - specific conductance and temperature ± 3%
    - turbidity < 10 NTU and ± 10 %
    - DO ± 10% (down to a detection limit of 0.5 mg/L)
    - ORP ± 10 mV
- The reporting limits presented are the lowest concentrations to which the instrument is considered linear and therefore accurate. Three consecutive readings below the reporting limits presented are considered to be stable.
- Readings should be recorded approximately every 5 minutes for flows in the range of 200 to 500 ml/min. Readings should be taken less frequently if the maximum flow rate is less than 100 ml/min because of the retention time in the flow-through cell. Each reading should represent a fresh aliquot of groundwater in the flow-through cell.
- Record the time at which the required minimum volume was removed, and record the total volume removed prior to sampling.

- If parameters do not stabilize, or turbidity remains greater than 5 NTU, or the minimum volume cannot be removed prior to the maximum purging time, contact the field team leader. Technical judgment will be used to ascertain when sampling should be commenced.

**5.3** Sampling with Peristaltic Pumps

The procedure for sampling with peristaltic pumps is as follows:

Determine the depth at which the samples will be collected by referring to the QAPP. Samples are frequently collected from the most-contaminated interval, as determined by previous profiling investigations, or from the lower part of the screened interval, or the midpoint of the saturated screened interval. If possible, keep the pump intake at least two feet above the bottom of the well to minimize mobilization of sediment that may be present at the bottom of the well.

Connect the necessary tubing to the pump, using a Y connector fitting and pinch valve to split the flow prior to the flow-through cell in order to collect an aliquot for turbidity:

- Measure a new section of pharmaceutical-grade, 3/16-inch inner diameter (ID) silicon tubing and attach it to the peristaltic pump head.
- Note that the length of silicon tubing in contact with the sample should be kept to a minimum.
- Measure a new section of 3/16-inch ID Teflon tubing to extend from the depth of the intended sampling location to the intake end of silicon tubing. To do this and avoid contamination of the tubing, it is recommended that a decontaminated water level measurement tape be used to measure the tubing as it is lowered into the well. The water level indicator may be lowered into the well with the tubing, or allowed to run onto the clean plastic on the ground outside of the well. Since the tubing is typically stored on a roll, straightening the tubing as you put it into the well will help avoid catching the tubing on any obstructions in the well, such as the top of the well screen. Once the tubing is lowered to the desired depth, immediately secure the free end of the Teflon tubing to prevent it dropping into the well. Using a piece of silicon tubing, connect the outflow end of the Teflon tubing to the HDPE Y-connector. Then, using several pieces of Teflon tubing, connect the pinch valve and check valve units to one end of the Y-connector (through which samples for turbidity will be collected) and connect the other end of the Y-connector to the intake of the flow-through cell.

Connect the electrical clamps from the pump to the appropriate terminals on the 12 volt battery.

Note that reversing the connections will typically cause the pump to run in reverse, which could push air into the well and should be avoided.

Re-measure and record the static groundwater level after the tubing has been placed in the well, and the water level has been allowed to stabilize again.

Determine the minimum purge volume required for the well. Samples should only be collected after the required volume has been removed from the well. For screen lengths of ten feet or less, a minimum volume of one saturated screen length plus drawdown volume must be removed. For screen lengths greater than ten feet, a minimum purge volume of three saturated screen lengths plus drawdown volume must be removed.

If the depth to water is less than the depth to the top of the screen, the screen is fully saturated and the minimum purge volume is one saturated screen length plus drawdown volume for screens of ten feet of less or three saturated screen lengths plus drawdown volume for screens greater than ten feet.

If the depth to water is greater than the depth to the top of the screen, calculate the well volume. Subtract the difference between the depth to water and the depth to the top of the screen from the well screen length to obtain the saturated well screen length. Round the saturated well screen length up to the nearest foot, and calculate the well volume using the volume per foot of screen length. Multiply the saturated well screen volume by three if the well screen length is greater than 10 feet.

Record the saturated well screen length and the saturated well screen volume on the sampling worksheet.

Commence purging at the slowest possible flow rate and slowly increase the speed until discharge occurs. The pump rate should be set to allow for maximum flow rate (100-1,000 milliliters per minute) with no drawdown. Refer to historical purge information for recharge information. Under no circumstances should the well be pumped dry and once pumping is begun, it should not be interrupted until all sample volume has been collected. Collect all purge water in a bucket or carboy.

Once the stagnant volume in the tubing has been removed (see below for volume equation), drawdown has stopped, and an acceptable flow rate has been established, begin monitoring indicator parameters and continue monitoring flow rate and water level. Record readings every three to five minutes, or as appropriate for the flow rate and flow-through cell volume. Use the water quality meter monitor the following: temperature, pH, specific conductance, DO, turbidity, and ORP. .

- Tubing radius = r = 0.0104 ft.
- Volume of tubing = $r^2$ x length of tubing = V (in ft3)
- $ft^3$ x 28.316 = liters
- In the event that the well has extremely low recharge such that the lowest purge rate possible (100 mL/min or more, if equipment cannot effectively purge that slowly) continues to dewater the well, do not allow a water level that was above the top of the screen to drop below it,
- do not allow a water level already below the top of the screen to drop further,
- do not allow the water level to drop below the pump intake,
- do not pump the well dry under any circumstances.

- Notify the field team leader of the situation. If all efforts to avoid dewatering the well have failed, a decision may be made to allow the well to recharge to a level sufficient to allow for collection of the necessary sample volume and to sample the well immediately.
- Record detailed notes concerning the sampling of the well.

Stop purging when all parameters have stabilized. Parameters are considered to have stabilized if, over three consecutive readings, the following criteria are met:

- pH ± 0.1 unit
- specific conductance and temperature ± 3%
- turbidity < 10 NTU and ± 10 %
- DO ± 10% (down to a detection limit of 0.5 mg/L)
- ORP ± 10 mV

The reporting limits presented are the lowest concentrations to which the instrument is considered linear and therefore accurate. Three consecutive readings below the reporting limits presented are considered to be stable.

Readings should be recorded approximately every 5 minutes for flows in the range of 200 to 500 ml/min. Readings should be taken less frequently if the maximum flow rate is less than 100 ml/min because of the retention time in the flow-through cell. Each reading should represent a fresh aliquot of groundwater in the flow-through cell.

Record the time at which the required minimum volume was removed, and record the total volume removed prior to sampling.

If parameters do not stabilize, or turbidity remains greater than 10 NTU, or the minimum volume cannot be removed prior to the maximum purging time, contact the field team leader. Technical judgment will be used to ascertain when sampling should be commenced.

**5.4** Sampling with Submersible Pumps

The procedure for sampling with submersible pumps is as follows:

Prior to placing any equipment in the well, measure and record the static water level as described in the water level measurement Standard operating procedure.

Note the water level in relation to the top of the screen. If the static water level is above the top of the screen, care should be taken to prevent the water level from dropping below the top of the screen.

Determine the depth at which the samples will be collected by referring to the QAPP. Samples are frequently collected from the most-contaminated interval, as determined by previous profiling investigations, or from the lower part of the screened interval, or the midpoint of the saturated

screened interval. If possible, keep the pump intake at least two feet above the bottom of the well to minimize mobilization of sediment that may be present at the bottom of the well.

Connect the pump to the power source. Submersible pumps are driven by an external power source.

If the use of a generator is required, it should be placed downwind of the sampling location to prevent exhaust from impacting the samples.

Care must be taken in handling the generator and gasoline to preclude cross-contamination of the samples and sampling equipment.

At a minimum, samplers must change gloves after handling the fuel or generator prior to sampling.

Carefully lower the pump to the desired sampling depth using the suspension cable. Take care to minimize disturbance and contact with the well walls which could knock rust or other deposits into the standing water.

Secure the pump using the suspension cable, and connect the ground from the pump.

Connect the purge water discharge line to the water quality meter using a splitter and pinch valve so that an aliquot of purge water can be obtained before the flow-through cell for turbidity measurements.

Connect the outflow end of the purge water line to the HDPE Y connector using a short piece of silicone tubing if necessary. Attach a piece of silicone tubing to one end of the Y and close it with a pinch value or check valve unit.

- Samples for turbidity measurements will be collected by opening this pinch valve.

Connect the other end of the Y connector to the lower of the two openings in the flow-through cell using Teflon tubing and short pieces of silicon tubing at the joints.

Connect a piece of Teflon tubing to the out flow of the flow-through cell to the purge bucket. Use a short piece of silicon tubing at the joint.

Be sure to use a piece of Teflon tubing sufficiently long to allow purge water to flow easily into the purge bucket.

Re-measure the static water level.

Determine the minimum purge volume required for the well.

Samples should only be collected after the required volume has been removed from the well.

For screen lengths of ten feet or less, a minimum volume of one saturated screen length plus drawdown volume must be removed.

For screen lengths greater than ten feet, a minimum purge volume of three saturated screen lengths plus drawdown volume must be removed.

If the depth to water is less than the depth to the top of the screen, the screen is fully saturated and the minimum purge volume is one saturated screen length plus drawdown volume for screens of ten feet of less or three saturated screen lengths plus drawdown volume for screens greater than ten feet.

If the depth to water is greater than the depth to the top of the screen, calculate the well volume. Subtract the difference between the depth to water and the depth to the top of the screen from the well screen length to obtain the saturated well screen length. Round the saturated well screen length up to the nearest foot, and calculate the well volume using the volume per foot of screen length. Multiply the saturated well screen volume by three if the well screen length is greater than 10 feet.

Record the saturated well screen length and the saturated well screen volume on the sampling worksheet.

Start the pump and begin purging at the slowest rate possible.

- Note the purge start time. Slowly increase the speed until discharge begins.
- The pump should be set to allow for adequate recharge such that a maximum flow rate with no drawdown is achieved (generally 100-1,000 mL/min).
- Refer to the historical flow controller settings for the well to select the starting controller pressure and intake and discharge intervals.

Collect all purge water in a bucket or carboy.

Measure the flow rate using a graduated cylinder and time piece and monitor the water level and pumping rate during purging.

Under no circumstances should purging be interrupted until all sample volume has been collected.

Once drawdown has stopped and an acceptable flow rate established, begin monitoring indicator parameters and continue monitoring flow rate and water level. Record reading every three to five minutes, or as appropriate for the flow rate and flow-through cell volume. Use the water quality meter to monitor the following: temperature, pH, specific conductance, DO, turbidity and ORP.

In the event that the well has extremely low recharge such that the lowest purge rate possible (100 mL/min or more, if equipment cannot effectively purge that slowly) continues to dewater the well, do not allow a water level that was above the top of the screen to drop below it, do not allow a water level already below the top of the screen to drop further, do not allow the water level to drop below the pump intake, and do not pump the well dry under any circumstances. Notify the field team leader of the situation. If all efforts to avoid dewatering the well have failed, a decision may be made to allow the well to recharge to a level sufficient to allow for collection of the necessary sample volume and to sample the well immediately. Record detailed notes concerning the sampling of the well.

Stop purging when all parameters have stabilized. Parameters are considered to have stabilized if, over three consecutive readings, the following criteria are met:

- pH ± 0.1 unit
- specific conductance and temperature ± 3%
- turbidity < 10 NTU and ± 10 %
- DO ± 10% (down to a detection limit of 0.5 mg/L)
- ORP ± 10 mV

The reporting limits presented are the lowest concentrations to which the instrument is considered linear and therefore accurate. Three consecutive readings below the reporting limits presented are considered to be stable.

Readings should be recorded approximately every 5 minutes for flows in the range of 200 to 500 ml/min. Readings should be taken less frequently if the maximum flow rate is less than 100 ml/min because of the retention time in the flow-through cell. Each reading should represent a fresh aliquot of groundwater in the flow-through cell.

Record the time at which the required minimum volume was removed, and record the total volume removed prior to sampling.

If parameters do not stabilize, or turbidity remains greater than 10 NTU, or the minimum volume cannot be removed prior to the maximum purging time, contact the field team leader. Technical judgment will be used to ascertain when sampling should be commenced.

**5.5** Sampling

Once purging has been completed, test for oxidants and sulfides as required for the analyses to be conducted and in accordance with standard operating procedures. Prior to commencing sampling,

- measure and record final water level, temperature, pH, specific conductance, DO, ORP, turbidity, and flow rate.
- disconnect the purge tubing from the flow-through cell, such that sample water will be collected directly from the tubing.

For the PPG Site 114 project, samples will be collected in the following order:

- VOCs
- Total Organic Halogens (TOX)
- Total Organic Carbon (TOC)
- SVOCs
- EPH

- PCBs
- Total Metals
- Dissolved Metals
- Phenols
- Cyanide
- Chloride
- Preserved Inorganics
- Non-preserved Inorganics

VOCs are always collected first, before other non-VOC parameters. During sample collection, allow the water to flow directly into and down the side of the sample container without allowing the tubing to touch the inside of the sample container or lid, in order to minimize aeration and maintain sample integrity.

**5.6** Post-Sampling Field Activities

Preserve the samples as per standard operating procedures for preservation. Immediately label the sample containers with the sample collection date and time and place them on ice. Complete the COC forms as soon as possible.

Cease pumping and disassemble the purging and sampling equipment.

Replace the well cap and lock the outer protective casing.

Decontaminate the sampling equipment as per standard operating procedures for decontamination.

Dispose of all purge water as per the site-specific work plan.

## 6.0 Quality assurance / quality control

The tubing and lines associated with sampling pumps are typically long and awkward to handle, and careful handling is required to prevent introduction of contaminants into the well. It is therefore preferable for set-up and installation of sampling equipment to be performed by a team of at least two people in order to prevent contamination of equipment to be introduced into the well.

Duplicate measurements cannot effectively be taken using the flow-though cell, since two consecutive measurements taken are not measuring the same sample, and flow cannot be interrupted. Water quality parameters obtained should be compared to historical readings, and potential instrument issues should be considered in the event of major differences.

**6.1** Pollution Prevention and Waste Management

Purge water volume is kept to a minimum through the use of the low-stress sampling procedures. When available, historical information on sampling rates for each well will be used in an attempt to minimize time spent determining the equilibrium flow rate and thereby minimizing purge water volume.

Lengths of Teflon tubing remove from each roll of tubing will be tracked to maximize use and minimize waste of remaining pieces.

Disposable tubing will be disposed of in accordance with the site-specific sampling and analysis plan.

Purge water will be containerized until purging and sampling activities at the well are completed. Purge water will then be disposed of in accordance with the site-specific sampling and analysis plan

## 7.0 Data and records management

All documentation will be conducted in accordance with standard documentation procedures.

Groundwater sampling information specific to each well will be recorded on the monitoring well sampling worksheet. An example monitoring well worksheet is included as Attachment 1 of this POP. Activities common to more than one well, samples collected, deviations from the sampling and analysis plan, and any other unusual occurrences will also be documented in the field logbook in accordance with standard documentation procedures.

## 8.0 Personnel qualifications and training

All field samplers are required to take the 40-hour OSHA health and safety training course and annual 8-hour refresher courses prior to engaging in any field collection activities.

For projects in New Jersey, field personnel collecting water quality indicator parameters (i.e., DO, pH, temperature, ORP, specific conductivity, and turbidity) must be certified by NJDEP for those parameters for which certification is offered as required by N.J.A.C. 7:26E-2.1(a)1.vii.

The entire sampling team should read and be familiar with the site Health and Safety Plan, all relevant POPs, and the SAP/QAPP (and the most recent amendments) before going onsite for the sampling event. It is recommended that the field sampling leader attest to the understanding of these site documents and that it is recorded.

Samplers will have a minimum of one-week's experience performing low-stress sampling prior to sampling without supervision

Project Operating Procedure

# Hydraulic Conductivity Tests – Pressure Transducer Method

## 1.0 Project Scope and applicability

### 1.1 Purpose and Applicability

This Project Operating Procedure (POP) describes the procedures for conducting rising head and falling head hydraulic conductivity tests (slug tests). Rising head/falling head tests are performed to determine the hydraulic conductivity of the soil or rock surrounding a monitoring well.

Hydraulic conductivity values are used for many purposes, including:

- To estimate rates of groundwater flow;
- To estimate responses of aquifers to applied stresses, such as pumping;
- To estimate the rate of movement of various chemicals in subsurface zones; and
- To construct and calibrate groundwater flow models.

In-situ tests to determine hydraulic conductivity can be conducted in open boreholes or in monitoring wells, and they can be variable-head tests or constant-head tests. The initial change in water levels required to begin the test can be produced by adding or removing a known volume of water using a pump or bailer, displacing water with a solid slug, or changing head conditions using pressurized gas. The water levels can be monitored using a water level tape or with a transducer. For the purpose of this POP, the method to perform a variable-head test in a monitoring well using a slug and transducer is outlined. Use of other test options must be fully described in the project-specific Work Plan.

Wells that contain high concentrations of contaminants or non-aqueous phase liquids may require specialized equipment which will not be damaged by the contaminants. Slug tests should not be performed in wells with non-aqueous phase liquid present.

### 1.2 General Principles

Hydraulic conductivity is a measure of the ability of a specific porous medium to transmit a specific fluid. Variable-head tests are performed by causing a sudden (instantaneous) rise or drop of the static water level in a well. Water levels are then monitored and recorded until the water level has returned to the condition prior to slug removal or insertion (i.e., static conditions) or sufficient data is collected to perform the hydraulic conductivity calculations.

### 1.3 Definitions

**1.3.1** Hydraulic Conductivity: The measure of the ability of a specific porous medium to transmit a specific fluid.

**1.3.2** Slug: Solid cylinder of teflon, PVC, or other material which is either lowered into the water inside the well to produce a temporary rise in the water level or removed to produce a temporary fall in the water level. If the cylinder is not solid, it should be sealed to prevent water leaking into the slug.

**1.3.3** Data Logger: A data logger is a computerized device which records in electronic memory the hydrostatic pressure (i.e., water level) measured by the transducer at specific, user-defined time intervals. The data logger and transducer may be combined in one device.

**1.3.4** Transducer: A probe lowered into a well that measures hydrostatic pressure which can be used to calculate the water level. The data logger and transducer may be combined in one device.

**1.3.5** Falling Head Test: Following the instantaneous rise in the static water level by inserting a slug, the drop in water level with respect to time is measured.

**1.3.6** Rising Head Test: Following the instantaneous lowering of the static water by extracting the slug, the rise of the water level with respect to time is measured.

**1.4** Quality Assurance Planning Considerations

Personnel shall follow specific quality assurance guidelines as outlined in the site-specific Work Plan and/or Quality Assurance Project Plan (QAPP), hereafter referred to as the project plans. Proper quality assurance requirements shall be provided which will allow project objectives to be met. Quality assurance requirements typically require the collection of both the rising head and falling head data for comparison or performing the same test twice, although falling head tests may not be required for monitoring wells screened in a water table aquifer. The minimum initial change in well or borehole water level achieved by the slug should be a minimum of one foot to ensure that the formation is sufficiently stressed so that meaningful hydraulic conductivity values can be determined.

The data collected during slug tests shall be reviewed and analyzed by a hydrogeologist or similarly qualified personnel. Many factors affect the appropriate interpretation of slug test data.

## 2.0 Health and safety considerations

Hydraulic conductivity testing may involve chemical hazards associated with the potentially contaminated groundwater the testing equipment comes in contact with. Adequate health and safety measures must be taken to protect project personnel from potential chemical exposures or other hazards. The health and safety considerations for the site, including both potential physical and chemical hazards, shall be addressed in the site-specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

**3.1** Not Applicable

## 4.0 Equipment and materials

Equipment required includes:

- Well records (boring, well logs, and well construction diagrams), if available
- Data logger(s)
- Transducer(s) with cable wire length sufficient to reach target depth and to reach from the well to the computer used to download data.
- Computer - with appropriate software and cables to download data from data logger
- Slugs - diameter dependent upon well diameter; the slug length is dependent on the length of the water column in the well but should provide a minimum of 1 foot displacement of the water column; slug materials may be specified by the project work plan.
- Nylon string
- Water level meter or steel tape
- Health and safety supplies
- Equipment decontamination supplies - Liquinox, buckets, brushes, plastic sheeting (around well to keep equipment clean), solvent (e.g., methanol), DI water, Kimwipes, and aluminum foil.
- Field logbook/standardized forms
- Pen

## 5.0 Procedures

**5.1** Office Preparation

**5.1.1** Review boring, well logs, and well construction diagrams to determine the geologic medium to be tested (sand, silt, clay, etc.) and well depth, depth-to-water, and screen placement.

**5.1.2** Determine what slug diameter and length are to be used on the well. The larger the slug, the greater the water displacement, which results in more comprehensive data capture. The diameter of the well, the length of the water column, and the medium to be tested, will determine which slug to use. The slug must be short enough to be completely submerged beneath the static water level, thin enough to be placed in the well and have sufficient room for the transducer cable and there must be room beneath the bottom of the slug for the transducer.

**5.1.3** Procure appropriate supplies based on well construction (transducer, cable length, slug sizes).

**5.2** General Site Preparation

**5.2.1** The monitoring wells to be tested should have been previously developed and had sufficient time to equilibrate before the hydraulic conductivity testing is conducted. The water level in tightly sealed wells may need to equilibrate once opened and exposed to the atmosphere. Well construction diagrams are necessary to determine the well diameter, sand pack thickness, the depth of the monitoring well and the screened interval.

**5.2.2** Measure the static water level and well depth in each well to be tested and record the level in the field logbook or on the standard form.

**5.2.3** Confirm slug diameter and length to use in well. Record the slug length and diameter in the field logbook or on the standard form for use during data evaluation.

**5.2.4** Record the make, model, and serial number of transducer and data logger in field log book or on the standard form. If data logger saves to an electronic file, record specified file name in field log book. File name protocols may be specified in the project plans.

**5.2.5** Connect the transducer cable to the data logger, and program the logger in accordance with manufacturer's instructions. If using a device where the transducer and logger are combined in one unit, connect the unit to the computer and program it in accordance with manufacturer's instructions. A logarithmic time or very short time interval (typically 3 seconds or less) should be used for recording slug test data. The specified time interval should be outlined in the project plans, and the transducer should have sufficient memory to record data for the entire test duration.

**5.2.6** Lower the transducer into the well. The transducer must be set at a level that will not be disturbed during the test, especially at the insertion or removal of the slug. Ideally, the entire slug length should be below the water surface; however, due to well geometry, this may not be possible. Also, if possible, the transducer should be set a few feet above the base of the well, above the level of any sediment that may be present and may potentially interfere with transducer readings. If these ideal conditions are not present, appropriate notes shall be recorded in the field note book or on the standard form.

**5.2.7** The cable of the transducer should be fixed (e.g., with tape or a clamp) at the top of the well to stabilize it and hold it in place.

**5.2.8** Allow the water level to equilibrate to the static level (i.e., the water level observed prior to installing the transducer). Monitor with the transducer and/or the water level meter.

**5.2.9** When the water has returned to the static water level following installation of the transducer, measure the depth to water using a water level meter and record in the field log book or on the standard form. Also, measure and record an instantaneous pressure reading, if possible. This allows pressure readings to be tied to hydraulic head values. If the data logger requires input of a reference elevation, enter into the data logger an appropriate reference elevation that corresponds to the measured

depth to water. Reference elevations may be set to zero, to the depth to water, or to a calculated hydraulic head (preferred). Record the reference elevation method in field log book or on the standard form.

**5.2.10** Tie nylon string to the slug and cut it to a length that will allow the top of the slug to be submerged beneath the static water level. The length of the string should not allow the slug to touch the transducer.

**5.3** Falling Head Test

**5.3.1** Lower the slug into the well so that the bottom of the slug is just above the water surface.

**5.3.2** Start the data logger recording and immediately lower the slug into the water in the well. The data logger should record a few measurements of static water level in the few seconds it takes to lower the slug. Care should be taken to lower the slug fast enough to produce a nearly instantaneous rise in the water level, but not so fast as to produce a wave when the slug enters the water. The top of the slug should be below the static water level, completely submerged.

**5.3.3** Monitor the data logger so that when the water level returns to the static level, the rising head test can be started (Sec. 5.4).

**5.3.4** If the hydraulic conductivity is low, it may take hours or more for the water level to return to static. In this situation the project hydrogeologist should determine a maximum duration for each test (typically 30 minutes).

**5.4** Rising Head Test

**5.4.1** When the falling head test is over, reset the data logger to begin a new test sequence. There should be no reason to re-set the reference elevation, unless the transducer moved during testing.

**5.4.2** Start the data logger recording. The data logger should record a few measurements of static water level prior to removal of the slug. The slug should be removed quickly so that an instantaneous fall in the water level occurs. Take care not to disturb the transducer when removing the slug.

**5.4.3** Terminate the rising head test when the water has returned to a static condition or the maximum test length duration determined by the project hydrogeologist has elapsed.

**5.4.4** If the hydraulic conductivity is low it may take hours or more for the water level to return to static. In this situation the project hydrogeologist should determine a maximum duration for each test (typically 30 minutes).

**5.5** Data Review and Download

**5.5.1** Some data logging equipment allows collected data to be reviewed and plotted on a graph in the field. Prior to moving to the next well location, it is beneficial to review the collected data to see if it appears acceptable. Common problems are that a well was insufficiently stressed (i.e., water level change from static less than 1 foot) or the transducer moved. Contact the project hydrogeologist if uncertain on the

acceptability of test results. If the data is not acceptable or the project plans require it, the test should be repeated. Make appropriate notes in field log book or on standard form.

The collected data from all tests must be downloaded into a computer for quantitative analysis. This may be performed in the field or in the office but in the field is preferred. If renting equipment, do not return until the project hydrogeologist can preliminarily review downloaded data for completeness. Follow manufacturer's instructions.

**5.6** Equipment Decontamination

**5.6.1** All equipment which comes into contact with the groundwater (slugs, transducer, and water level tape) shall be decontaminated in accordance with POP PPG 014 Decontamination of Field Equipment before moving to the next location. The string, plastic sheeting, and any health and safety supplies (e.g. gloves) shall be properly disposed of in accordance with site requirements.

**5.7** Data Analysis

**5.7.1** Several methods are available for analyzing data obtained from hydraulic conductivity tests. Most methods incorporate graphical techniques, such as semi-log and log-log plots, to evaluate the data and select values for the calculations. Computer software is available to aid in evaluation.

Inherent in all analytical methods are simplifying assumptions concerning the aquifer properties and test methods. When selecting a particular analytical method, it is important to consider the basic assumptions that underlie the mathematical expressions. In many cases it may be advisable to evaluate the data using several methods and examine the range of hydraulic conductivities that are obtained. When reporting a calculated in-situ hydraulic conductivity, the analytical method(s) used should be referenced.

One of the major issues in determining the method to use is whether the aquifer is a water table (unconfined) aquifer or a confined aquifer. Falling head tests may overestimate hydraulic conductivity in water table aquifers if the screened interval is not fully submerged. Although the tests may be performed under such conditions and analyzed for comparative purposes to rising head tests, the limitations of falling head tests conducted in a water table aquifer should be appropriately considered and noted when reporting results or computing average values.

## 6.0 Quality assurance / quality control

The slug test and data analysis shall be performed under the supervision of a hydrogeologist or other qualified personnel. A hydrogeologist shall review all calculations and results.

Both rising and falling head tests or replicate tests may be conducted for quality control. If the rising and falling head results are not comparable, assess whether the transducer recorded accurate data.

The falling head test is not accurate for wells with screens that bracket the stabilized water table, because they will overestimate hydraulic conductivity. These tests may be performed in water table wells, but the results should not be used quantitatively.

## 7.0 Data and records management

Documentation for the field component of hydraulic conductivity tests shall include a minimum of the following:

- Project and site identification
- Measured groundwater levels (with water level tape and/or electronic files from the data logger)
- Slug dimensions
- Data logger / transducer number or instrument identification number/model
- Reference elevations, if available
- Other data logger programming inputs
- Relevant dates and times for start / finish and subsequent water-level measurements
- Weather conditions
- Identities of personnel performing the measurements
- Description of any events or conditions that could impact the quality of the test results

The information shall be recorded in a field logbook or on a standard field form (see Attachment 1). Analysis and results of the tests shall be documented in a technical memorandum and/or report as specified in the project plans.

## 8.0 Personnel qualifications and training

The field technician shall be properly trained in the process of hydraulic conductivity measurement and shall have specialized training and supervision in using the transducer and data loggers.

The slug test and data analysis shall be performed by or under the supervision of a hydrogeologist or other qualified personnel. A hydrogeologist shall review all calculations and results.

**8.1** Project Manager

The project manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources, and guidance necessary to perform the measurements in accordance with this POP and the project plans.

**8.2** Field Technician

It is the responsibility of the field technician to be familiar with the general principles of hydraulic conductivity testing and the testing equipment. The field technician is responsible for verifying that the equipment is in proper operating condition prior to use and for implementing the measurement procedures in accordance with this POP and the project plans.

**8.3** Project Hydrogeologist

It is the responsibility of the project hydrogeologist to provide guidance to the field technician necessary to perform the measurements in accordance with this POP and the project plans and to perform and/or supervise the analysis of the data collected.

# Project Operating Procedure
# Chip Sampling

## 1.0 Scope and Applicability

**1.1** This Project Operating Procedure (POP) defines the procedures for the collection of chip samples to determine surficial contamination on porous surfaces (e.g., cement, brick, wood). These procedures are intended for samples to be analyzed for non-volatile analyses (e.g., PCBs, TCDD, and TCDF), and should not be used for volatile organic compound (VOC) analysis. Sample points should be carefully chosen and should be based on site history, manufacturing processes, personnel practices, obvious contamination, and available surface area. Suggested sampling points include floors near process vessels and storage tanks, loading dock areas, etc. The sampling area should be large enough to provide a sufficient amount of sample for analysis (smaller sample volumes cause higher detection limits). To facilitate the calculations once the analytical data is received, the area sampled should be measured.

## 2.0 Health and Safety Considerations

**2.1** The health and safety considerations for the work associated with this POP, including both potential physical and chemical hazards, will be addressed in the site specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

**3.1** Cross contamination from sampling equipment will be prevented by using sampling equipment constructed of stainless steel that is adequately decontaminated between samples.

## 4.0 Equipment and Materials

To collect a chip sample, the following equipment is needed:

- Ruler, measuring tape, measuring wheel, or other similar measuring device
- Chalk
- Disposable nitrile gloves, safety glasses, and other PPE required in the site-specific HASP.
- Decontaminated beryllium copper or stainless steel chisel
- Hammer or electric hammer

- Dedicated natural bristle brush and a dust pan lined with aluminum foil or one that is dedicated, decontaminated and constructed of a pre-approved material which will not interfere with the contaminants of concern
- Glass sample containers
- Field logbook and pen with indelible ink

## 5.0 Procedures

**5.1** Mark off the sample collection location with chalk and measure the area.

**5.2** Don safety glasses, a new pair of disposable gloves, and any other PPE required in the site-specific HASP.

**5.3** Using the decontaminated chisel and hammer, break up the surface of the location to be sampled. An effort should be made to avoid scattering pieces out of the marked sampling area boundary. Any pieces that fall outside the sampling area should not be used. The area should be chipped to less than ¼" and preferably ⅛".

**5.4** Record how deep chips were taken in the field logbook or field data sheet.

**5.5** Collect the chipped pieces using a dedicated, decontaminated dustpan and natural bristle brush and transfer the sample directly into the sample container.

**5.6** Repeat the process for each location to be sampled. Use new or decontaminated equipment at each location. Outer gloves must be changed before each sample is collected.

**5.7** Decontaminate the sampling equipment in accordance with POP PPG 014 Decontamination of Field Equipment.

## 6.0 Quality Assurance / Quality Control

**6.1** Sampling personnel should follow specific quality assurance guidelines as outlined in the QAPP and/or Work Plan. Proper quality assurance requirements should be provided which will allow for collection of representative samples from representative sampling points. Quality assurance requirements outlined in the QAPP and/or Work Plan typically suggest the collection of a sufficient quantity of field duplicate, field blank, and other samples.

**6.2** Quality control requirements are dependent on project-specific sampling objectives. The QAPP and/or Work Plan will provide requirements for equipment decontamination (frequency and materials), sample preservation and holding times, sample container types, sample packaging and shipment, as well as requirements for the collection of various quality assurance samples such as trip blanks, field blanks, equipment blanks, and field duplicate samples.

## 7.0 Data and Records Management

**7.1** All data and information (e.g., sample collection method used) must be documented on field data sheets or within site log books with permanent ink.

**7.2** Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records.

**7.3** Records associated with the activities described in this POP will be maintained according to the document management policy for the project.

## 8.0 Personnel Qualifications and Training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this POP.

**8.1.2** The entire sampling team should read and be familiar with the site Health and Safety Plan, all relevant POPs, and the QAPP and/or Work Plan (and the most recent amendments) before going onsite for the sampling event. It is recommended that the field sampling leader attest to the understanding of these site documents and that it is recorded.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

**8.2.2** The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

Project Operating Procedure

# Wipe Sampling

## 1.0 Scope and Applicability

**1.1** This Project Operating Procedure (POP) defines the procedures for the collection of wipe samples to determine surficial contamination on non-porous surfaces (e.g., metal, glass). Sample points should be carefully chosen and should be based on site history, manufacturing processes, personnel practices, obvious contamination, and available surface area. Sample points should be carefully chosen and should be based on site history, manufacturing processes, personnel practices, obvious contamination, migration pathways and available surface area. Suggested sampling points include process vessels, ventilation ducts and fans, exposed beams, windowpanes, etc. The area wiped should be large enough to provide a sufficient amount of sample for analysis (smaller sample volumes cause higher detection limits).

## 2.0 Health and Safety Considerations

**2.1** The health and safety considerations for the work associated with this POP, including both potential physical and chemical hazards, will be addressed in the site specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

**3.1** To facilitate the collection of a wipe sample, a 3” x 3” gauze pad should be utilized. The use of filter paper for wipe sampling is not recommended. Filter paper will tend to rip and crumble if the surface wiped is slightly rough. If filter paper is to be used, it should be 4” diameter heavy gauge paper, such as Whatman #4 Filter Paper.

**3.2** Occasionally samples are desired from painted or waxed surfaces. Since hexane may degrade the finish or pick up interfering substances, an alternate solvent should be used. In this case, methanol or distilled/deionized water for semi-volatiles, pesticides and PCBs and distilled and deionized water alone for metals should be used. Surface interference should be recorded in the field logbook.

When samples are submitted for analysis, the laboratory should be instructed to rinse the sample jars with the appropriate extraction or digestion solvent, depending on the analysis to be performed, when transferring the sample to the extraction/digestion glassware. This will ensure that the entire sample has been removed from the sample container.

## 4.0 Equipment and Materials

To collect a chip sample, the following equipment is needed:

- Ruler or measuring tape
- Disposable nitrile gloves, safety glasses, and other PPE required in the site-specific HASP.
- Sterile, wrapped, 3" x 3" gauze pad
- Glass sample containers with appropriate pesticide-grade solvent or distilled/deionized water
- Field logbook and pen with indelible ink

## 5.0 Procedures

**5.1** Mark off the sample collection location. It is recommended that an area be premeasured (e.g. 25 cm x 25 cm) to allow for easier calculation of the final results. However, this is not always feasible and may be done after the area is wiped.

**5.2** Don safety glasses, a new pair of disposable gloves, and any other PPE required in the site-specific HASP.

**5.3** Remove the gauze pad from its sterile wrapping and soak it with the appropriate solvent. The solvent of choice may change based upon the analytes of interest and surface being sampled. Gauze pads for semi-volatiles, pesticide and PCB samples should be moistened in a 1:4 acetone/hexane mixture and those for metals with distilled/deionized water. The gauze pad should be soaked and excess squeezed out immediately before the collection of each sample. **Use of presoaked pads is not acceptable.** Alternate solvents may be acceptable for certain parameters, however, their approval for use will be at the discretion of NJDEP.

**5.4** Wipe the entire area to be sampled once in the horizontal direction and once in the vertical direction, applying moderate pressure. Wipe the entire area so that all the sample material is picked up.

**5.5** Place the gauze pad into the sample container.

**5.6** Repeat the process for each location to be sampled. Outer gloves must be changed before each sample is collected.

**5.7** A blank must always be collected for each wipe-sampling event at the frequency specified in the QAPP and/or Work Plan in order to ensure the quality of the data. The blank will help to identify potential introduction of contaminants from the pad, solvent, sample container or ambient air conditions. Collect the wipe blank as follows:

- Don a new pair of nitrile gloves
- Wet a gauze pad with the solvent or distilled/deionized water (for each collection parameter) and place the pad directly into the sample bottle.

## 6.0 Quality Assurance / Quality Control

**6.1** Sampling personnel should follow specific quality assurance guidelines as outlined in the QAPP and/or Work Plan. Proper quality assurance requirements should be provided which will allow for collection of representative samples from representative sampling points. Quality assurance requirements outlined in the QAPP and/or Work Plan typically suggest the collection of a sufficient quantity of field duplicate, field blank, and other samples.

**6.2** Quality control requirements are dependent on project-specific sampling objectives. The QAPP and/or Work Plan will provide requirements for equipment decontamination (frequency and materials), sample preservation and holding times, sample container types, sample packaging and shipment, as well as requirements for the collection of various quality assurance samples such as trip blanks, field blanks, equipment blanks, and field duplicate samples.

## 7.0 Data and Records Management

**7.1** All data and information (e.g., sample collection method used) must be documented on field data sheets or within site log books with permanent ink.

**7.2** Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records.

**7.3** Records associated with the activities described in this POP will be maintained according to the document management policy for the project.

## 8.0 Personnel Qualifications and Training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this POP.

**8.1.2** The entire sampling team should read and be familiar with the site Health and Safety Plan, all relevant POPs, and the QAPP and/or Work Plan (and the most recent amendments) before going onsite for the sampling event. It is recommended that the field sampling leader attest to the understanding of these site documents and that it is recorded.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

**8.2.2** The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

Project Operating Procedure

# Concrete Core Sampling

## 1.0 Scope and Applicability

**1.1** This Project Operating Procedure (POP) defines the procedure that will be used for the collection of concrete core samples. Selected concrete cores will be removed from floor slabs, foundations, and other concrete structures. Subsamples of the cores will be obtained at various depth intervals using the procedure described hereinafter.

**1.2** A carbide drill bit attached to a rotary hammer will be used to obtain cuttings from a solid core. The cuttings are taken from the side of the core at selected intervals, based on visual evidence of chromium or other criteria (such as depth). Cores containing a thin band (<0.25 inch) of chromium at the bottom, will be chip sampled using a beryllium chisel. If the core disintegrates during sampling, the remaining portions will be pulverized with a beryllium hammer to obtain a representative sample.

## 2.0 Health and Safety Considerations

**2.1** The health and safety considerations for the work associated with this POP, including both potential physical and chemical hazards, will be addressed in the site specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

**3.1** Cross contamination from sampling equipment will be prevented by using sampling equipment constructed of stainless steel that is adequately decontaminated between samples.

## 4.0 Equipment and Materials

- Decontaminated carbide drill bit, 1 inch to 2 inch in diameter and approximately six inches in length;
- Power rotary hammer;
- Decontaminated beryllium copper or stainless steel chisel;
- Hammer;
- Engineers rule;
- Bristle brush, dedicated;
- Decontaminated glass bowl;

- Decontaminated/dedicated polyethylene or Teflon spoon;
- Polyethylene sheeting;
- Disposable nitrile gloves;
- Safety glasses; and
- Field logbook and pen with indelible ink

## 5.0 Procedures

**5.1** Photograph, in color, the core from the top, bottom and side. Record the photograph number in the field logbook. Sketch the specifics of each core (dimensions, staining,etc) in the field logbook.

**5.2** Brush the loose dirt from the bottom of the core.

**5.3** Measure the dimensions of the core to be sampled and select the sample intervals for the collection of the drill cuttings. Sketch specifics of the sample intervals in the field logbook.

**5.4** Beginning at the top of the core, drill holes around the perimeter at the first sampling interval and collect the cuttings on the polyethylene sheeting or in the glass bowl. Drill each hole approximately 3/8ths of the way through the core and stop. Rotate the core 90 degrees and drill again. Continue drilling holes around the perimeter of the core until enough sample cuttings are produced to sufficiently fill the sample collection jar for the analyses requested.

If the core breaks during drilling, collect the remaining portion of that interval with a dedicated beryllium chisel and hammer, and pulverize the chips on new polyethylene sheeting. The final pieces should be no larger than 1 centimeter in diameter.

**5.5** Transfer the sample cuttings from the sheeting or bowl to the sampling jar with a polyethylene or Teflon spoon.

**5.6** Repeat the process for each interval. Use new or decontaminated equipment at each interval. Outer gloves must be changed before each sample is collected.

**5.7** Decontaminate the sampling equipment in accordance with POP PPG 014 Decontamination of Field Equipment.

## 6.0 Quality Assurance / Quality Control

**6.1** Sampling personnel should follow specific quality assurance guidelines as outlined in the QAPP and/or Work Plan. Proper quality assurance requirements should be provided which will allow for collection of representative samples from representative sampling points. Quality assurance requirements outlined in the QAPP and/or Work Plan typically suggest the collection of a sufficient quantity of field duplicate, field blank, and other samples.

**6.2** Quality control requirements are dependent on project-specific sampling objectives. The QAPP and/or Work Plan will provide requirements for equipment decontamination (frequency

and materials), sample preservation and holding times, sample container types, sample packaging and shipment, as well as requirements for the collection of various quality assurance samples such as trip blanks, field blanks, equipment blanks, and field duplicate samples.

## 7.0 Data and Records Management

**7.1** All data and information (e.g., sample collection method used) must be documented on field data sheets, boring logs, or within site log books with permanent ink.

**7.2** Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records.

**7.3** Records associated with the activities described in this POP will be maintained according to the document management policy for the project.

## 8.0 Personnel Qualifications and Training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this POP.

**8.1.2** The entire sampling team should read and be familiar with the site Health and Safety Plan, all relevant POPs, and the QAPP and/or Work Plan (and the most recent amendments) before going onsite for the sampling event. It is recommended that the field sampling leader attest to the understanding of these site documents and that it is recorded.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

**8.2.2** The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

# Project Operating Procedure
# Sweep Sampling

## 1.0 Scope and Applicability

**1.1** This Project Operating Procedure (POP) defines the procedures for the collection of sweep samples to determine surficial contamination on porous (e.g., asphalt) or non-porous (e.g., metal) surfaces. These procedures are intended for samples to be analyzed for non-volatile analyses (e.g., PCBs, TCDD, and TCDF), and should not be used for volatile organic compound (VOC) analysis. Sweep sampling allows collection of dust/residue samples that may help in the assessment of contaminant determination and delineation. Sample points should be carefully chosen and should be based on site history, manufacturing processes, personnel practices, obvious contamination, migration pathways and available surface area. Suggested sampling points include ventilation systems where dust can collect, floor surfaces near process vessels and storage tanks, or street gutters where contaminated sediments may have migrated and accumulated. The area sampled should be large enough to provide a sufficient amount of sample for analysis.

## 2.0 Health and Safety Considerations

**2.1** The health and safety considerations for the work associated with this POP, including both potential physical and chemical hazards, will be addressed in the site specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

**3.1** Cross contamination from sampling equipment will be prevented by using dedicated sampling equipment and/or sampling equipment constructed of stainless steel that is adequately decontaminated between samples.

## 4.0 Equipment and Materials

To collect a sweep sample, the following equipment is needed:

- Disposable nitrile gloves, safety glasses, and other PPE required in the site-specific HASP.
- Dedicated natural bristle brush
- Stainless steel spatula or dedicated spatula
- Dust pan lined with aluminum foil or one that is dedicated, decontaminated and constructed of a pre-approved material which will not interfere with the contaminants of concern

- Glass sample containers
- Field logbook and pen with indelible ink
- Camera (optional)

## 5.0 Procedures

**5.1** Identify the location to be sampled and document its description in the field log book or field data sheets. If necessary, take a picture of the location.

**5.2** Don safety glasses, a new pair of disposable gloves, and any other PPE required in the site-specific HASP.

**5.3** Using the dedicated natural bristle brush, sweep all residue in the area to be sampled into a decontaminated or dedicated dustpan.

**5.4** Use the decontaminated stainless steel or dedicated spatula to transfer the sample from the dustpan to the sample bottle(s).

**5.5** Repeat the process for each location to be sampled. Use dedicated or decontaminated equipment at each location. Outer gloves must be changed before each sample is collected.

**5.1** Decontaminate the sampling equipment in accordance with POP PPG 014 Decontamination of Field Equipment.

## 6.0 Quality Assurance / Quality Control

**6.1** Sampling personnel should follow specific quality assurance guidelines as outlined in the QAPP and/or Work Plan. Proper quality assurance requirements should be provided which will allow for collection of representative samples from representative sampling points. Quality assurance requirements outlined in the QAPP and/or Work Plan typically suggest the collection of a sufficient quantity of field duplicate, field blank, and other samples.

**6.2** Quality control requirements are dependent on project-specific sampling objectives. The QAPP and/or Work Plan will provide requirements for equipment decontamination (frequency and materials), sample preservation and holding times, sample container types, sample packaging and shipment, as well as requirements for the collection of various quality assurance samples such as trip blanks, field blanks, equipment blanks, and field duplicate samples.

## 7.0 Data and Records Management

**7.1** All data and information (e.g., sample collection method used) must be documented on field data sheets or within site log books with permanent ink.

**7.2** Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records.

**7.3** Records associated with the activities described in this POP will be maintained according to the document management policy for the project.

## 8.0 Personnel Qualifications and Training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this POP.

**8.1.2** The entire sampling team should read and be familiar with the site Health and Safety Plan, all relevant POPs, and the QAPP and/or Work Plan (and the most recent amendments) before going onsite for the sampling event. It is recommended that the field sampling leader attest to the understanding of these site documents and that it is recorded.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

**8.2.2** The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

Project Operating Procedure

# Decontamination of Field Equipment

## 1.0 Project Scope and applicability

### 1.1 Purpose and Applicability

This POP describes the methods to be used for the decontamination of field equipment used in the collection of environmental samples. The list of field equipment may include a variety of items used in the collection of soil and/or water samples, such as split-spoon samplers, trowels, scoops, spoons, bailers and pumps. Heavy equipment such as drill rigs and backhoes also require decontamination, usually in a specially constructed temporary decontamination area.

Decontamination is performed as a quality assurance measure and a safety precaution. Improperly decontaminated sampling equipment can lead to misinterpretation of environmental data due to interference caused by cross-contamination. Decontamination protects field personnel from potential exposure to hazardous materials. Decontamination also protects the community by preventing transportation of contaminants from a site.

This POP emphasizes decontamination procedures to be used for decontamination of reusable field equipment. Occasionally, dedicated field equipment such as well construction materials (well screen and riser pipe) or disposable field equipment (bailers or other general sampling implements) may also require decontamination prior to use. The project-specific work plan should indicate the specific decontamination requirements for a particular project.

Respective state or federal agency (regional offices) regulations may require specific types of equipment or procedures for use in decontamination of field equipment. The project manager should review the applicable regulatory requirements, if any, prior to the start of the field investigation program.

### 1.2 General Principles

Decontamination is accomplished by manually scrubbing, washing, or spraying equipment with detergent solutions, tap water, distilled/deionized water, steam and/or high pressure water, or solvents. The decontamination method and agents are generally determined on a project-specific basis and must be stated in the Quality Assurance Project Plan (QAPP) and/or Work Plan.

Generally, decontamination of equipment is accomplished at each sampling site between collection points. Waste decontamination materials such as spent liquids and solids will be collected and managed as investigation-derived waste for later disposal. All decontamination materials, including wastes, should be stored in a central location so as to maintain control over the quantity of materials used or produced throughout the investigation program.

## 2.0 Health and safety considerations

Decontamination procedures may involve chemical exposure hazards associated with the type of contaminants encountered or solvents employed and may involve physical hazards associated with decontamination equipment. When decontamination is performed on equipment which has been in contact with hazardous materials or when the quality assurance objectives of the project require decontamination with chemical solvents, the measures necessary to protect personnel must be

addressed in the project Health and Safety Plan (HASP). This plan must be approved by the project Health and Safety Officer before work commences, must be distributed to all personnel performing equipment decontamination, and must be adhered to as field activities are performed.

## 3.0 Interferences

Improper decontamination can result is sample contamination and affect the accuracy of data.

## 4.0 Equipment and materials

- Decontamination agents (per work plan requirements):
  - LIQUI-NOX, ALCONOX, or other phosphate-free biodegradable detergent,
  - Tap water,
  - Distilled/deionized water,
  - Nitric acid and/or hydrochloric acid,
  - Methanol and/or hexane, acetone, isopropanol.
- Health and Safety equipment
- Chemical-free paper towels
- Waste storage containers: drums, 5-gallon pails w/covers, plastic bags
- Cleaning containers: plastic buckets or tubs, galvanized steel pans, pump cleaning cylinder
- Cleaning brushes
- Pressure sprayers
- Squeeze bottles
- Plastic sheeting
- Aluminum foil
- Field logbook and pen with indelible ink

## 5.0 Procedures

**5.1** General Preparation

**5.1.1** It should be assumed that all sampling equipment, even new items, are contaminated until the proper decontamination procedures have been performed on them or unless a certificate of analysis is available which demonstrates the items cleanliness.

Field equipment that is not frequently used should be wrapped in aluminum foil, shiny side out, and stored in a designated "clean" area. Small field equipment can also be

stored in plastic bags to eliminate the potential for contamination. Field equipment should be inspected and decontaminated prior to use if the equipment appears contaminated and/or has been stored for long periods of time. Unless customized procedures are stated in the QAPP and/or Work Plan for decontamination of equipment, the standard procedures specified in this POP shall be followed.

**5.1.2** Establish the decontamination station within an area that is convenient to the sampling location. If single samples will be collected from multiple locations, then a centralized decontamination station, or a portable decontamination station should be established.

**5.1.3** An investigation-derived waste (IDW) containment station should be established at this time also. The project-specific work plan should specify the requirements for IDW containment. In general, decontamination solutions are discarded as IDW between sampling locations. Solid waste is disposed of as it is generated.

**5.2** Sampling conducted using bailers

**5.2.1** Field decontamination of bailers will not be conducted on this project. Only dedicated disposable bailers or laboratory decontaminated bailers will be used for sample collection in accordance with the FSPM.

**5.3** Decontamination for Organic Analyses

**5.3.1** This procedure applies to soil sampling and groundwater sampling equipment used in the collection of environmental samples submitted for organic constituents analysis. Examples of relevant items of equipment include split-spoons, trowels, scoops/spoons, bailers, and other small items. Submersible pump decontamination procedures are outlined in Section 5.4.

**5.3.2** Decontamination is to be performed before sampling events and between sampling points.

**5.3.3** After a sample has been collected, remove all gross contamination from the equipment or material by brushing and then rinsing with available tap water. This initial step may be completed using a 5-gallon pail filled with tap water. Steam or a high-pressure water rinse may also be conducted to remove solids and/or other contamination.

**5.3.4** Wash the equipment with a phosphate-free detergent and tap water solution. This solution should be kept in a 5-gallon pail with its own brush.

**5.3.5** Rinse with tap water or distilled/deionized water until all detergent and other residue is washed away. This step can be performed over an empty bucket using a squeeze bottle or pressure sprayer.

**5.3.6** Rinse with methanol or other appropriate solvent using a squeeze bottle or pressure sprayer. Rinsate should be collected in a waste bucket.

**5.3.7** Rerinse with deionized water to remove any residual solvent. Rinsate should be collected in the solvent waste bucket.

**5.3.8** Allow the equipment to air-dry in a clean area or blot with chemical-free paper towels before reuse. Wrap the equipment in tin foil and/or seal it in a plastic bag if it will not be reused for a while.

**5.3.9** Dispose of soiled materials and spent solutions in the designated IDW disposal containers.

**5.4** Decontamination for Inorganic (Metals) Analyses

**5.4.1** This procedure applies to soil sampling equipment used primarily in the collection of environmental samples submitted for inorganic constituents analysis. Examples of relevant items of equipment include split-spoons, trowels, scoops/spoons, bailers, and other small items.

**5.4.2** For plastic and glass sampling equipment, follow the steps outlined in 5.2 above, however, use a 10% nitric acid solution (acid in water) in place of the solvent rinse.

**5.4.3** For metal sampling equipment, follow the steps outlined in 5.2 above, however, use a 10% hydrochloric acid solution (acid in water) in place of the solvent rinse.

**5.5** Decontamination of Submersible Pumps

**5.5.1** This procedure will be used to decontaminate submersible pumps before and between ground-water sample collection points. This procedure applies to both electric submersible and bladder pumps. This procedure also applies to discharge tubing if it will be reused between sampling points.

**5.5.2** Prepare the decontamination area if pump decontamination will be conducted next to the sampling point. If decontamination will occur at another location, the pump and tubing may be removed from the well and placed into a clean trash bag for transport to the decontamination area. Pump decontamination is easier with the use of 3-foot tall pump cleaning cylinders (i.e., Nalgene cylinder) for the various cleaning solutions, although the standard bucket rinse equipment may be used.

**5.5.3** Sample tubing shall not be decontaminated in the field. Only dedicated tubing will be used for each well and disposed of upon completion of well sampling.

**5.5.4** Once the decontamination station is established, the pump should be removed from the well and the discharge tubing and power cord coiled by hand as the equipment is removed. If any of the equipment needs to be put down temporarily, place it on a plastic sheet (around well) or in a clean trash bag. If a disposable discharge line is used it should be removed and discarded at this time.

**5.5.5** As a first step in the decontamination procedure, use a pressure sprayer with tap water to rinse the exterior of the pump, discharge line, and power cord as necessary. Collect the rinsate and handle as IDW.

**5.5.6** Cut a short piece of dedicated tubing and attach it to the pump. Place the pump into a pump cleaning cylinder or bucket containing a detergent solution (detergent in tap water). Bend the tubing so that decontamination fluids can be recirculated back into the bucket. Holding the tubing/power cord, pump solution through the pump system. A minimum of one gallon of detergent solution should be pumped through the system. Collect the rinsate and handle as IDW.

**5.5.7** Place the pump into another cylinder/bucket containing a 10% solution of solvent (methanol, or other designated solvent) in distilled/deionized water. Bend the tubing so that decontamination fluids can be recirculated back into the bucket. Pump until the detergent solution is removed in accordance with the NJDEP FSPM, Chapter 2A,

Section 2.4.4, page 17. Circulate the rinse solution for three or more system cycles. Collect the rinsate and handle as IDW.

**5.5.8** Place the pump into another cylinder/bucket containing distilled/deionized water. Bend the tubing so that decontamination fluids can be recirculated back into the bucket. Pump a minimum of 3 to 5 pump system volumes (pump and tubing) of water through the system. Vary the pump speed during decontamination and briefly raise the pump to introduce air during the decontamination procedure. Collect the rinsate and handle as IDW.

**5.5.9** Remove the pump from the cylinder/bucket and if the pump is reversible, place the pump in the reverse mode to discharge all removable water from the system. If the pump is not reversible the pump and discharge line should be drained by hand as much as possible. Collect the rinsate and handle as IDW.

**5.5.10** Refill the cylinder/bucket with clean potable water and run pump for 3 to 5 pump system volumes. Collect the rinsate and handle as IDW. Then, using a pressure sprayer with distilled/deionized water, rinse the exterior of the pump, discharge line, and power cord thoroughly, shake all excess water, then place the pump system into a clean trash bag for storage. If the pump system will not be used again right away, the pump itself should also be wrapped with aluminum foil before placing it into the bag.

**5.6** Decontamination of Bladder Pumps

**5.6.1** Most bladder pumps cannot be easily decontaminated in the field due to their unique construction. For that reason, bladder pumps are not employed on a well-to-well basis **unless** they are constructed with easy to clean parts and *disposable* bladders. If they are constructed with disposable bladders, proper decontamination should include removal, disposal, and replacement of the used bladder and a thorough eight-step decontamination procedure. Field cleaning of bladder pumps is acceptable only if the following conditions are met: 1) the bladder pump housing is constructed of stainless steel with an internal disposable bladder and 2) either the eight-step, Cold Regions decontamination method or the ultra clean decontamination method is employed as discussed in the NJDEP FSPM.

**5.7** Decontamination of Peristaltic Pumps

**5.7.1** A peristaltic pump is a self-priming suction lift (negative air pressure) pump utilized at the ground surface, which consists of a rotor with ball bearing rollers. One end of dedicated tubing is inserted into the well. The other end is attached to a short length of flexible tubing, which has been threaded around the rotor, out of the pump, and connected to a discharge tube. The liquid moves totally within the tubing, thus no part of the pump contacts the liquid. Tubing used for well evacuation may also be used for sample collection. Teflon®-lined polyethylene tubing is recommended for sampling. Tubing will be discarded and properly disposed of after each sample is collected.

**5.8** Decontamination of Large Equipment

**5.8.1** Consult the QAPP and/or Work Plan for instruction on the location of the decontamination station and the method of containment of the wash solutions. On large projects usually a temporary decontamination facility (decontamination pad) is required which may include a membrane-lined and bermed area large enough to

drive heavy equipment (drill rig, backhoe) onto with enough space to spread other equipment and to contain overspray. Usually a small sump with pump is necessary to collect and contain rinsate. A water supply and power source is also necessary to run steam cleaning and/or pressure washing equipment.

**5.8.2** Upon arrival and prior to leaving a sampling site, all heavy equipment such as drill rigs, trucks, and backhoes should be thoroughly cleaned and then the parts of the equipment which come in contact or in close proximity to sampling activity should be decontaminated. This can be accomplished in two ways, steam cleaning or high pressure water wash and manual scrubbing. Following this initial cleaning, only those parts of the equipment which come in close proximity to the sampling activities (i.e., auger stems, rods, backhoe bucket) must be decontaminated in between sampling events.

**5.8.3** Occasionally, well construction materials such as well screen and riser pipe may require decontamination before the well materials are used. These materials may be washed in the decontamination pad, preferably on a raised surface above the pad (i.e., on sawhorses), with clean plastic draped over the work surfaces. Well materials usually do not require a multistep cleaning process as they generally arrive clean from the manufacturer. Usually, a thorough steam-cleaning of the interior/exterior of the well materials will be sufficient. The QAPP and/or Work Plan should provide specific guidance regarding decontamination of well materials.

## 6.0 Quality assurance / quality control

### 6.1 General Considerations

Sampling personnel should follow specific quality assurance guidelines as outlined in the QAPP. The QAPP guidelines typically require collection of equipment blank samples in order to determine the effectiveness of the decontamination procedure.

The decontamination method, solvent, frequency, location on site and the method of containment and disposal of decontamination wash solids and solutions are dependent on site logistics, site-specific chemistry, and nature of the contaminated media to be studied and the objectives of the study. Each topic must be considered and addressed during development of a decontamination strategy and should be outlined in the QAPP and/or Work Plan.

### 6.2 Solvent Selection

There are several factors which need to be considered when deciding upon a decontamination solvent. The solvent should not be an analyte of interest. The sampling equipment must be resistant to the solvent. The solvent must be evaporative or water soluble or preferably both. The applicable regulatory agency may have specific requirements regarding decontamination solvents. The QAPP and/or Work Plan should specify the type of solvent to be used for a particular project.

The analytical objectives of the study must also be considered when deciding upon a decontamination solvent. Pesticide-grade methanol is the solvent of choice for general organic analyses. It is relatively safe and effective. Hexane, acetone, and isopropanol are sometimes used as well. A 10% nitric acid in deionized water solution is the solvent of choice for general metals analyses. Nitric acid can be

used only on Teflon, plastics and glass. If used on metal equipment, nitric acid will eventually corrode the metal and lead to the introduction of metals to the collected samples. Dilute hydrochloric acid is usually preferred over nitric acid when cleaning metal sampling equipment.

Equipment decontamination should be performed a safe distance away from the sampling area so as not to interfere with sampling activities but close enough to the sampling area to maintain an efficient working environment. If heavy equipment such as drill rigs or backhoes are to be decontaminated, then a central decontamination station should be constructed with access to a power source and water supply.

### **6.3** Field Blank Sample Collection

General guidelines for quality control check of field equipment decontamination usually require the collection of one field blank from the decontaminated equipment per day. The QAPP should specify the type and frequency of collection of each type of quality assurance sample.

Field blanks are generally made by pouring laboratory-supplied deionized water into, over, or through the freshly decontaminated sampling equipment and then transferring this water into a sample container. Field blanks should then be labeled as a sample and submitted to the laboratory to be analyzed for the same parameters as the associated sample. Field blank sample numbers, as well as collection method, time and location should be recorded in the field notebook.

## 7.0 Data and records management

Specific information regarding decontamination procedures should be documented in the project-specific field notebook. Documentation within the notebook should thoroughly describe the construction of each decontamination facility and the decontamination steps implemented in order to show compliance with the project work plan. Decontamination events should be logged when they occur with the following information documented:

- Date, time and location of each decontamination event
- Equipment decontaminated
- Method
- Solvents
- Notable circumstances
- Identification of field blanks and decontamination rinsates
- Method of blank and rinsate collection
- Date, time and location of blank and rinsate collection
- Disposition of IDW

Repetitive decontamination of small items of equipment does not need to be logged each time the item is cleaned.

## 8.0 Personnel qualifications and training

All sampling technicians performing decontamination must be properly trained in the decontamination procedures employed, the project data quality objectives, health and safety procedures and the project QA procedures. Specific training or orientation will be provided for each project to ensure that personnel understand the special circumstances and requirements of that project. Field personnel should be health and safety certified as specified by OSHA (29 CFR 1910.120(e)(3)(i)) to work on sites where hazardous materials may be present.

### **8.1** Sampling Technician

It is the responsibility of the sampling technician to be familiar with the decontamination procedures outlined within this POP and with specific quality assurance, and health and safety requirements outlined within project-specific work plans (HASP, QAPP, Work Plan, etc.). The sampling technician is responsible for decontamination of field equipment and for proper documentation of decontamination activities. The sampling technician is also responsible for ensuring that decontamination procedures are followed by subcontractors when heavy equipment requires decontamination.

### **8.2** Field Project Manager

The field project manager is responsible for ensuring that the required decontamination procedures are followed at all times. The project manager is also responsible for ensuring that subcontractors construct and operate their decontamination facilities according to project specifications. The project manager is responsible for collection and control of IDW in accordance with project specifications.

Project Operating Procedure

# Procedures for Acid Testing of Green-Gray Mud and COPR

## 1.0 Scope and Applicability

**1.1** This Project Operating Procedure (POP) is for acid testing of material suspected to be Green-Gray Mud or chromite ore processing residue (COPR). This procedure will be used on material that cannot be definitively identified as Green-Gray Mud or COPR through other techniques (e.g., visual, magnetic, XRF). The results of the procedure will be used as part of a weight-of-evidence approach to determine whether the material in question is Gray/green mud or COPR.

High levels of calcium (i.e., percent levels) are expected in Green-Gray Mud and possibly COPR. Hydrochloric acid (HCl) will be used in a controlled manner to determine if the suspected material contains calcium and is potentially Green-Gray Mud or COPR. The HCl will be added to the suspected material in a drop-wise manner and the material will be observed for a reaction.

## 2.0 Health and Safety Considerations

**2.1** The health and safety considerations for the work associated with this POP, including both potential physical and chemical hazards, will be addressed in the site-specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

**2.2** Due to the use of hydrochloric acid (HCl) this procedure, field personnel will be required to wear safety glasses and gloves when performing this procedure. The plastic dropper bottle for the HCl must be stored in a plastic container that is lined with acid neutralizing sorbent paper. The plastic container and dropper bottle must be labeled as HCl and also have a United Nations (UN) 1789 label (Figure 1). Refer to the job safety analysis (JSA) for this activity in the site-specific HASP for more detail.

## 3.0 Interferences

**3.1** Soils that contain carbonate salts/minerals other than calcium will also react with the HCl and may lead to false conclusion that calcium is present.

## 4.0 Equipment and Materials

- 16 ounce (oz) clear glass jars

- Labeled plastic dropper bottle containing 1:1 HCl (i.e., 6 normal [N] HCl)
- Labeled plastic storage container lined with acid neutralizing sorbent paper for plastic dropper bottle
- Extra acid neutralizing sorbent paper for spills
- Plastic scoop
- Nitrile gloves
- Safety glasses
- Field logbook and pen
- Site HASP
- Project Feasibility Study Work Plan (FSWP)
- Camera (optional)

## 5.0 Procedures

**5.1** Don safety glasses and nitrile gloves as instructed in the site-specific HASP.

**5.2** Use the plastic scoop to transfer a small amount (e.g., 5-10 grams) of the suspected material into a 16 oz clear glass jar.

Remove the plastic dropper bottle from its plastic storage container. Carefully open the dropper bottle and drop 2-3 drops of HCl onto the suspected material in the 16 oz clear glass jar. Observe the material for any reaction. If calcium or other carbonate salts/minerals are present, effervescing/foaming should occur. Observe the material for approximately 30 seconds and record the observations in the field logbook. If necessary, a camera can be used to photodocument the presence or absence of a reaction.

**5.3** Once the test is complete, replace the cap on the dropper bottle, and return the dropper bottle to its plastic storage container.

**5.4** Wait for any reaction that is occurring to subside, and dispose of the material in the soil stockpile.

**5.5** Rinse the 16 oz clear glass jar and dispose of the rinse water in accordance with the investigative derived waste (IDW) procedures for the site.

## 6.0 Quality Assurance / Quality Control

**6.1** The field notes generated from this procedure will be reviewed by the sampling team leader, project manager, or designee.

## 7.0 Data and Records Management

**7.1** Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records.

**7.2** Records associated with the activities described in this POP will be maintained according to the document management policy for the project.

## 8.0 Personnel Qualifications and Training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this POP.

**8.1.2** Each person who performs this procedure will be trained by someone familiar with the procedure such that the procedure is performed in a consistent manner throughout the duration of the project. No field staff will perform this procedure without one-on-one training from another field staff that is familiar with the procedure.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

**8.2.2** The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

# Project Operating Procedure
# Wet Sieve

## 1.0 Scope and Applicability

**1.1** This Project Operating Procedure (POP) defines basic techniques for field screening of wet soil to determine the percent by weight of COPR particles and grain size. Sieving will be done wet to avoid generation of dust.

## 2.0 Health and Safety Considerations

**2.1** The work will be conducted in accordance with the site specific HASP and the Job Safety Analysis. This procedure is specifically designed to prevent dusty conditions during soil handling. Due to the possibility of release of volatile organics and contamination of equipment, soil with MGP material and/or photoionizing detector readings over 10 ppm will not be processed.

## 3.0 Interferences

**3.1** Debris (twigs, roots, trash, etc) that is not removed from the soil prior to and during screening can lead to high bias in the amount for each screen. The addition of water may slightly increase the estimated weight of COPR nodules. The goal is to measure weight percent COPR to ±5%.

## 4.0 Equipment and Materials

- 5-gallon buckets
- 5-gallon bucket with holes drilled and lined with fine mesh
- 2-4 bricks
- Level D PPE with tyvek suit with booties and nitrile gloves
- Ear plugs
- Half face respirator (in the case of exceedence of air action levels)
- Scale capable of weighing at least 50 lbs ± 0.1 pounds
- Shovel
- 2”, 1”, ½”, ¼” and No. 7 sieve screens

- Additional screens No. 14 and No. 200
- Plastic tubs ( One 14-gallon tub and at least 10 smaller tubs)
- Munsell color chart
- Field Screening for Grain Size Field Form (Attachment 1)
- Field logbook and pen
- Site HASP
- Work Plan
- Screen Shaker
- Camera (optional)

## 5.0 Procedures

**5.1** Prior to initiation of sieving prepare the following equipment:

**5.1.1** A 5-gallon bucket with holes and mesh. Drill small diameter holes (3/8") in the bottom on the sides of a 5-gallon bucket. Adhere a fine mesh (No. 200) to the bottom and sides of the inside of the bucket. Make sure the mesh is smaller than the smallest tray being used in the shaker.

**5.1.2** Obtain two dedicated plastic containers for each sieve tray. Weigh each container and note the weight in both the field book and on the container. For each sieve size mark two plastic containers with the sieve size. You should have two plastic containers for each sieve size; one for the entire sieve size and one for chromium nodules.

**5.1.3** Place the sieve machine in a bermed area on a plastic sheet.

**5.2** Don the modified Level D PPE including tyvek suit with booties, nitrile gloves and hearing protection as instructed by the site-specific HASP.

**5.3** Inspect the five gallon bucket prior to processing. Each bucket should have a grid designation and a depth interval. These should be noted on the sieve collection form. Review the soil classification data sheet. If the sample contains MGP material or PID readings over 10 ppm, do not process and call the project manager.

**5.4** Place the 5-gallon bucket on the scale and record the weight on the field form.

**5.5** Soil will be collected from the excavation under a separate POP (see the Sample Collection POP for details).

**5.6** Weight the bucket containing the soil and record the weight on the field form.

**5.7** Fill the bucket with water so that it covers the soil. Allow the soil to soak in the water for at least 15 minutes to allow soil to soften.

**5.8** Place two bricks in the bottom of a 14 gal or greater plastic tub. Place the 5-gallon bucket with holes and mesh on top of the bricks.

**5.9** Transfer the soil and water that has been soaking in the bucket into the 5-gallon bucket with holes. Allow the water to drain from the bucket but make sure the soil does not dry out. Make sure the bottom of the bucket is not sitting in standing water (add more bricks if necessary to insure the bucket is out of the water).

**5.10** Dispose of the water in the frac tanks for off-site disposal.

**5.11** Weigh the filled 5-gallon bucket and record the weight on the field form. Subtract the initial weight of the bucket to determine the actual soil (and water) weight.

**5.12** Pour the contents of the 5-gallon bucket into the top of the Gilson Porta-Screen. If the sample weight was greater than 60 lbs. only pour half of the soil into the shaker at a time. If the sample is split be sure to combine the total at the end. **Follow the instructions provided by Gilson when operating the shaker** (Attachment 2).

**5.13** Transfer the contents of each tray into a separate pre-weighed dedicated grain size container. Weigh and record the weight on the field form making sure to subtract the container weight.

**5.14** Sort through each container and pull out the chromium nodule. Place the chromium nodules in another pre-weighed container. Once all the chromium nodules are separated from the soil, weigh and record the weight of each chromium nodule container making sure to subtract the container weight. COPR nodules are typically round and 1/8 to ¼ inch in size. Large particles and irregular shapes are possible. Suspect nodules can be scrapped or crushed for closer examination. Compare visual clues to sample COPR pellets.

**5.15** Calculate percent weight of COPR by the following equation:

Total weight of COPR pellets / Weight lf soil tested (prior to wetting) x 100%

**5.16** Dispose of soil and chromium nodules in the soil stockpile for off-site disposal.

## 6.0 Quality Assurance / Quality Control

**6.1** The field forms and field notes generated from this procedure will be reviewed by the sampling team leader, project manager, or designee.

## 7.0 Data and Records Management

**7.1** Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records.

**7.2** Records associated with the activities described in this POP will be maintained according to the document management policy for the project.

## 8.0 Personnel Qualifications and Training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this POP.

**8.1.2** Each person who performs this procedure will be trained by someone familiar with the procedure such that the procedure is performed in a consistent manner throughout the duration of the project. No field staff will perform this procedure without one-on-one training from another field staff that is familiar with the procedure.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

**8.2.2** The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

# SAFETY INSTRUCTIONS
# GILSON PORTA-SCREEN®

WHETHER YOU ARE THE OWNER, EMPLOYER, OPERATOR, OR MAINTENANCE PERSON FOR THIS MACHINE, SAFETY IS YOUR RESPONSIBILITY. YOU ARE RESPONSIBLE FOR OPERATING AND MAINTAINING THIS EQUIPMENT IN COMPLIANCE WITH THESE INSTRUCTIONS AND FOR USING COMMON SENSE. YOU SHOULD ALWAYS REVIEW AND COMPLETELY UNDERSTAND THESE SAFETY AND OPERATING INSTRUCTIONS BEFORE USING THIS MACHINE.

⚠ **DANGER**: This machine operates on electrical current. Improper use could result in electric shock, electrocution, injury by explosion, or even death.

1. **ALWAYS** make sure the motor and electrical components are appropriate and properly configured for your intended use and available power source. Porta-Screens are normally wired for 115 volts 60Hz and come with a 1/4 hp non-explosion-proof motor.

2. **ALWAYS** check electrical wiring for loose connections and for pinched or frayed wiring.

3. **ALWAYS** ground the Porta-Screen®. Connect its three-pronged plug to a properly-wired, three-pronged, grounded receptacle with appropriate electrical current for the machine.

4. **ALWAYS** disconnect and lock out the power supply before performing maintenance or repairs on your machine.

⚠ **DANGER**: The 1/4 hp, 115-volt motor of the Porta-Screen® has internal thermal protection. Therefore, the motor will automatically shut off if overloaded. The motor will restart by itself after cooling unless disconnected from its power source during cool-down.

⚠ **DANGER**: Do not use the Porta-Screen® in an explosive or hazardous atmosphere. It is not explosion-proof.

***Warning:*** Operate only in a properly-ventilated area.

***Warning:*** Level the Porta-Screen® before operation.

***Warning:*** Stop the Porta-Screen® if excessive vibration or machine movement occurs.

***Warning:*** Always take care not to pinch your fingers between the clamp levers and the machine frame.

***Warning:*** Do not operate without all guards and covers in place.

***Warning:*** Keep all parts of your body away from moving parts of the machine while it is operating.

***Warning:*** Do not wear loose clothing which might be caught in moving parts of the machine.

***Warning:*** Wear safety glasses, protective clothing, and hearing protection. Wear approved NIOSH/MSHA respirator as required by the sample to prevent your inhaling any dust which may be considered hazardous.

# Gilson Porta-Screen®

The Gilson Porta-Screen® is a portable shaker for field control of construction aggregates and for quality control in asphalt and ready-mix plants. It is designed for best separation in the 2" (50.8mm) to No. 16 (1.18mm) range. Model PS-3 holds five screen trays and a pan; PS-4's capacity is seven trays and a pan.

## 1.0 Unpacking & Installation

The Porta-Screen®, packed for shipment, weighs between 225 and 255 lbs, depending on the model and the number of trays packed inside. Use equipment to adequately to handle this weight safely.

1. The Porta-Screen® is shipped in a cardboard carton. Before you accept the shipment, check the carton for visible damage. Note any damage on the freight bill, and proceed with inspection.

2. Place the carton on its side so that you can remove the staples from the bottom. Open the bottom flaps and set the machine upright again. Lift off the carton and set it aside until you are sure that the Porta-Screen® is in acceptable condition.

3. Check the machine for shipping damage. If you find concealed damage after you have signed for the Porta-Screen®, call the delivering carrier immediately for an inspection. Save all packing materials, and leave the Porta-Screen® as it is.

4. Check the tag on the electric motor of the Porta-Screen® to be sure that the machine is wired as ordered.

5. Release clamping pressure on the Porta-Screen® trays by rotating the clamp levers outward and upward 180˚.

6. Remove trays by sliding them out the front of the machine.

7. Choose your operating site:

   A. The Porta-Screen® requires a properly-wired, three-pronged, grounded receptacle with appropriate electrical current for the machine.

   B. Choose a well-ventilated site.

   C. Set the Porta-Screen® on a solid, stable floor, platform, or other surface.

8. When you have placed the Porta-Screen® in its operating location, and each time you move it, level the unit by adjusting the three leveling legs.

   To extend a leg, place your foot on the edge of the pad, and lift up on the machine above the leg.

   To contract a leg, depress the leg lock tab, which extends from the case above each footpad.

   Use the bullseye level in the top frame crossbar as a guide.

   After you have placed the Porta-Screen® into service, observe the distribution of sample material in the trays at the end of a test. If the material is not evenly distributed, re-level the machine.

9. Reinstall the trays in the Porta-Screen®. Leave them unclamped.

10. Do not plug in the Porta-Screen® until you are ready to use it.

## 2.0 Operation

WHETHER YOU ARE THE OWNER, EMPLOYER, OPERATOR, OR MAINTENANCE PERSON FOR THIS MACHINE, SAFETY IS YOUR RESPONSIBILITY. YOU ARE RESPONSIBLE FOR OPERATING AND MAINTAINING THIS EQUIPMENT IN COMPLIANCE WITH THESE INSTRUCTIONS AND FOR USING COMMON SENSE. YOU SHOULD ALWAYS REVIEW AND COMPLETELY UNDERSTAND THESE SAFETY AND OPERATING INSTRUCTIONS BEFORE USING THIS MACHINE.

***Warning:*** Operate only in a properly ventilated area.

***Warning:*** Level the Porta-Screen® before operation.

***Warning:*** Stop the Porta-Screen® if excessive vibration or machine movement occurs.

***Warning:*** Always take care not to pinch your fingers between the clamp levers and the machine frame.

***Warning:*** Do not operate without all guards and covers in place.

***Warning:*** Keep all parts of your body away from moving parts of the machine while it is operating.

***Warning:*** Do not wear loose clothing which might be caught in moving parts of the machine.

***Warning:*** Wear safety glasses, protective clothing, and hearing protection. Wear approved NIOSH/MSHA respirator as required by the sample to prevent your inhaling any dust which may be considered hazardous.

**Procedure:**

Read and be sure you understand all safety, operating, and timer instructions, as well as specifications and procedures for your test.

1. Check to see that the Porta-Screen® is level.
2. Select and load the appropriate trays.

   Fill all the slots: five trays and pan for the PS-3
   seven trays and pan for the PS-4

   The Porta-Screen® will not clamp or operate properly unless fully loaded with trays. If your test requires fewer trays than the capacity of the Porta-Screen®, you may insert the required trays in the upper slots with the pan immediately below. Then fill the lower slots with extra trays.
3. Clamp the trays by rotating the clamp levers so that they point down.
4. Pour your sample into the top tray. Refer to the sample capacity information and be sure not to overload the Porta-Screen®.
5. Connect the three-pronged plug into a properly-wired, grounded receptacle with appropriate electrical current.
6. Set and activate the timer.
7. When the machine stops, unclamp the trays by rotating the clamp levers so they point up. Remove and empty the trays, following the directions in your test specifications.
8. When you have finished your test, unplug the machine. Do not reconnect power until you are ready to use the machine again.
9. Store clean, empty trays in the unit, leaving them unclamped.
10. Re-level the machine before the next use.

## 3.0 Sample Capacity

Capacity of the Porta-Screen® depends on the specifications of the test and the type and size of the material being tested. For any given sample, the Porta-Screen's maximum capacity is determined by the tray which has the largest load at the end of the test. This is the limiting tray.

**Coarse Aggregates:**

Minimum quantity of sample is usually established by the specifications of the test procedure. For example, ASTM C-136 "Specification for the Sieve or Screen Analysis of Fine and Coarse Aggregates" calls for the minimum weight of the test sample of coarse aggregates (density such as limestone or gravel) as follows:

| Normal Maximum Size of Particle mm (in) | Minimum Sample Weight kg (lb) |
|---|---|
| 9.5 (3/8) | 1 (2) |
| 12.5 (1/2) | 2 (4) |
| 19.0 (3/4) | 5 (11) |
| 25.0 (1) | 10 (22) |
| 37.5 (1-1/2) | 15 (33) |
| 50 (2) | 20 (44) |
| 63 (2-1/2) | 35 (77) |

These guidelines on minimum sample size quantities are for representative samples. Always take a much larger amount, perhaps from several spots in a storage bin or stockpile. Then combine and reduce them to the correct quantity by splitting.

With coarse series trays, (2" to No. 4), the limiting tray should have no more than one layer of particles over the wire cloth at the end of the test. Therefore, lightweight aggregates or coal must be tested in lower sample weights. High-density ores or pellets may be tested in larger amounts by weight. Many light materials are also soft, and test times should be limited to avoid degradation of the sample.

Most samples of up to 2" topsize can be handled in a single batch without difficulty. We do not recommend the use of trays with mesh sizes above 1-1/2", since larger particles become wedged in the mesh and make it difficult to remove the trays.

**Fine Aggregates:**

With fine series trays, (No. 8 to No. 200), the limiting tray should contain no more than approximately four grams per square inch of sieve surface at the end of a test. Assuming that the material is about the density of sand, there will be approximately 800 grams maximum on the limiting tray.

Since the Porta-Screen® is designed primarily for use in the 2" to No. 20 range, separations in finer sizes will not be as precise. If you are testing materials exclusively in the fine range, we recommend equipment specifically designed for this purpose, such as the Gilson Model SS-8R Sieve Shaker.

## 4.0 Maintenance & Disassembly

READ AND BE SURE YOU UNDERSTAND ALL SAFETY AND MAINTENANCE INSTRUCTIONS BEFORE PERFORMING MAINTENANCE ON YOUR PORTA-SCREEN®.

ALWAYS DISCONNECT AND LOCK OUT ELECTRIC POWER BEFORE PERFORMING MAINTENANCE.

**Clamping System:**

1. DISCONNECT AND LOCK OUT ELECTRIC POWER.
2. Load the Porta-Screen® with trays and pan, filling all the slots.
3. Rotate the clamp levers (#38) so that they point down.
4. Locate the clamp adjusting nuts (#9), which are on the lower ends of the four clamp tension rods (#7).
5. Tighten the nuts only enough to prevent the trays from rattling when the machine is operating.

**Lubrication:**

1. DISCONNECT AND LOCK OUT ELECTRIC POWER.

2. Remove and set aside trays and pan.

3. Remove upper case cover.

4. Connection Rod Bearing:
   Lubricate the connecting rod bearing (#52) after every 80 to 100 hours of operation.

   a. Rotate drive shaft (#20) slightly by hand until the grease fitting at the lower end of the connecting rod (#50) is accessible. (Grease fitting may be pointing either to the front or to the back of the Porta-Screen®).

   b. Apply a small amount of any good-quality bearing grease.

   c. Proceed to shaft bearing lubrication.

5. Shaft Bearings:
   There are two bearings (#47), front and rear, on the drive shaft (#20), and two bearings (#41), front and rear, on each of the two counterweight shafts (#12, 13). Some Porta-Screens have sealed shaft bearings; others have shaft bearings with grease fittings. If the shaft bearings on your machine have grease fittings, lubricate the bearings after every 80 to 100 hours of operation.

   a. WITH ELECTRIC POWER DISCONNECTED AND LOCKED OUT, and trays, pan, and upper case cover removed, remove lower front and rear case covers.

   b. Apply a small amount of any good-quality bearing grease.

   c. Reassemble in reverse order.

6. Motor Bearings: Lubricate annually.

   a. Remove trays, pan, and upper case cover.

   b. Remove lower front and rear case covers.

   c. Find and remove the oil plugs at each end of the motor.

   d. Insert a few drops of oil.

   e. Replace plugs.

   f. Reassemble in reverse order.

7. Idler Pulley Bearings:
   These sealed bearings (#62) do not require lubrication.

**Belts:** The Drive Belt (#22) should fit snugly. If the belt is too tight, it will soon wear out, causing bearings to wear and resulting in noisy operation. A loose belt may cause the unit to run too slowly or to slip. Keep the drive pulley (#21) and motor pulley (#60) aligned so that the drive belt is straight.

The Timing Belt (#16) should fit tightly.

**Access to Belts:**

1. DISCONNECT AND LOCK OUT ELECTRIC POWER.

2. Remove and set aside trays and pan.

3. Remove all case covers.

4. Drive Belt:
   Check tension by pressing on the span of the belt. If properly adjusted, the belt should be deflected 1/64th of the value of the distance between the pulleys. To adjust or remove, loosen the motor mounting bolts (#61); and the motor will slide up, loosening the belt tension.

   a. To adjust, move the motor up or down until the belt tension is correct. Retighten the nuts.

   b. Or remove the loosened belt if it is worn, and install a new one. Obtain the correct tension by moving the motor up or down. Retighten the nuts.

   c. Continue or reassemble.

5. Timing Belt:
   Check tension by pressing on the span of the belt. The belt should be tight. To adjust or remove the timing belt, loosen the two idler bracket mounting screws (#45). Loosen the nut on the adjusting screw (#46).

   a. To tighten: Turn in the adjusting screw to pull the bracket (#17) down and increase tension on the belt. Retighten the nut to hold the bracket in position. Reassemble.

   b. To replace: Loosen the adjusting screw to permit the idler bracket to move upward, loosening the tension on the timing belt so that you can remove it. Before reinstalling belt,

(1) Rotate drive shaft (#20) until the connecting rod (#50) is at its highest position.

(2) Rotate counterweight shafts (#12, #13) until counterweights are at their lowest position.

(3) Fit the belt around the left counterweight shaft pulley, around the timing pulley (#49), above the right counterweight shaft pulley, and around the idler pulley (#19).

(4) Tighten the idler bracket adjusting screw until the timing belt is tight, making certain that you do not change the position of the shafts. Lock the idler bracket in position with the nut. Tighten the bracket mounting screws.

(5) Reassemble.

DO NOT PLUG IN THE PORTA-SCREEN® UNTIL YOU ARE READY TO USE IT.

**Bearing Replacement:**

1. Guide Bearing Assemblies:
   The Porta-Screen® has three guide bearing assemblies: each has a housing and guide bushing. The two upper guide bearings (#34) are mounted to the top frame crossbar. The lower guide bearing (#59) is mounted to the underside of the vibrating unit.

   If you notice side-to-side movement of the vibrating unit during operation, inspect the guide bearings and replace them if necessary. We recommend replacement of all three assemblies at the same time.

   a. DISCONNECT AND LOCK OUT ELECTRIC POWER.

   b. Remove and set aside trays and pan.

   c. Remove top frame screws (#2), and lift off top frame crossbar (#1).

   d. Upper:
      (1) Remove mounting screws (#35) to detach bearing housing (#34).

      (2) Replace with new bearing housing assembly.

   e. Lower:
      (1) Remove all case covers.

      (2) Remove the connecting rod mounting bolt (#24).

      (3) Lift the entire vibrating unit assembly up and out of the Porta-Screen® frame.

      (4) Remove mounting screws (#56) to detach bearing housing unit (#59).

      (5) Replace with new bearing housing assembly.

   f. Reassemble in reverse order.

DO NOT PLUG IN THE PORTA-SCREEN® UNTIL YOU ARE READY TO USE IT.

2. Connecting Rod & Drive Shaft Bearings:
   The connecting rod (#50) can be replaced as an assembly, or you can press out and replace its bearing and bushing (#52).

   The drive shaft (#20) has front and rear bearings (#47). We recommend replacement of both front and rear bearings as a set.

   a. DISCONNECT AND LOCK OUT ELECTRIC POWER.

   b. Remove and set aside trays and pan.

   c. Remove top frame screws (#2).

   d. Lift off top frame crossbar (#1).

   e. Remove all case covers.

   f. Remove the connecting rod mounting bolt (#24).

   g. Lift the entire vibrating unit assembly up and out of the Porta-Screen® frame.

   h. Loosen the motor mounting bolts to release tension on the drive belt, and remove the drive belt from its pulleys.

   i. Loosen the setscrew in the drive pulley (#21), and slide the pulley off the drive shaft.

   j. Loosen the setscrew in the rear drive shaft bearing.

   k. Loosen the idler bracket mounting and adjusting screws (#45, 46) to release tension on the timing belt.

   l. Remove the timing belt (#16).

   m. Loosen the setscrew in the drive shaft pulley (#49), and slide the pulley off the drive shaft.

   n. Remove the mounting screws from the front drive shaft bearing (#47).

   o. Hold onto the top of the connecting rod (#50) while you pull the drive shaft out from the front of the machine with the front bearing attached.

   p. Remove the connecting rod (#50).

   q. Install new connecting rod assembly or press new bushing and bearing into existing connecting rod.

   r. Replace drive shaft bearings if needed.

   s. Continue or reassemble in reverse order. When replacing timing belt, refer to timing belt instructions and be sure that counterweights are aligned properly.

DO NOT PLUG IN THE PORTA-SCREEN® UNTIL YOU ARE READY TO USE IT.

3. Counterweight Shaft Bearings:
   Each of the two counterweight shafts (#12, 13) has a front and a rear bearing (#41). We recommend replacement of both bearings on a shaft. If you have disassembled the Porta-Screen® to replace the connecting rod and/or drive shaft bearings, skip to step h. Otherwise, disassemble as follows:

   a. DISCONNECT AND LOCK OUT ELECTRIC POWER.

   b. Remove and set aside tray and pan.

   c. Remove top frame screws (#2).

   d. Lift off top frame crossbar (#1).

   e. Remove all case covers.

   f. Remove the connecting rod mounting bolt (#24).

   g. Lift the entire vibrating unit assembly up and out of the Porta-Screen® frame.

   h. Loosen the idler bracket mounting and adjusting (#45, 46) to release tension on the timing belt.

   i. Remove the timing belt (#16).

   j. Loosen the bolts on the rear counterweight clamp bracket (#43), and remove the counterweight from the shaft.

   k. Loosen the setscrew which holds the rear bearing to the counterweight shaft.

   l. Remove the mounting screws (#42) which hold the front counterweight shaft bearing (#41) to the main frame.

   m. Pull the counterweight shaft from the front of the machine with its front counterweight, pulley, and front bearing all attached.

   n. Reinstall parts as needed.

   o. Reassemble in reverse order. When replacing timing belt, refer to timing belt instructions and be sure that the counterweights are aligned properly.

DO NOT PLUG IN THE PORTA-SCREEN® UNTIL YOU ARE READY TO USE IT.

4. Wire Cloth:
   Check condition of wire cloth both before and after operation. Test results can be only as accurate as the size of wire cloth openings. Always replace with testing grade wire cloth only.

   Testing grade wire cloth is a precision-made material and should be treated with care. The ASTM E-11 specification permits only very slight variations in average opening and wire diameter. Abrasion due to normal use and/or improper cleaning and handling can cause the wire cloth to be out of specification to a considerable degree before it appears worn. Check it frequently to be sure that it conforms to your test specifications.

   Wire cloth life can be extended by establishing proper procedures for handling, cleaning, and storage of trays. The Porta-Pan Accessory is helpful in the repetitive sequence of emptying trays, cleaning wire cloth, and weighing sample fractions.

   Wire cloth may eventually sag, reducing its effective screening area. Wire sizes 2" to No. 14 are rigid and self-supporting. Trays for No. 16 through No. 80 wire cloth contain three wire cloth support strips. No. 100 and finer trays have supporting backup cloth to minimize wear and distortion. When you replace No. 16 and finer wire cloth, always use support strips or backup cloth as indicated.

## 5.0 Parts List

| | PARTS | NO. REQUIRED |
|---|---|---|
| | ***Outer Case & Frame Parts*** | |
| 1 | Top frame cross bar | 1 |
| 2 | Top frame screw & lock washer | 4 |
| 31 | Bullseye level with cushion washer | 1 |
| 36 | Bullseye level adjusting screws | 3 |
| 27 | Leg lock tab | 3 |
| 33 | Leg lock tab spring | 3 |
| 65,28 | Leveling leg (65), with adjusting screw pad, nut & washer | 3 |
| 29 | Main frame | 1 |
| 30 | Vibrating unit assembly | |
| | Upper case cover | 2 |
| 11A | Lower case cover, front | 1 |
| | Lower case cover, rear | 1 |
| | ***Upper Guide Bearing Assembly Parts*** | |
| 34 | Upper guide bearing housing with guide bushing | 2 |
| 35 | Upper guide bearing mounting screw & lock washer | 4 |
| 4 | Upper guide bearing pin & set screw | 2 |
| | ***Clamping Assembly Parts, Right & Left*** | |
| 5A | Clamp lever with mounting bracket 6F left side | 1 |
| 5B | Clamp lever with mounting bracket 6F right side | 1 |
| 38 | Clamp lever handle grip | 2 |
| 6R | Rear clamp lever mounting bracket | 2 |
| 39 | Clamp lever mounting bracket screw & lock washer | 8 |
| 7 | Clamp tension rod | 4 |
| 40 | Clamp tension rod retainer clip, screw and lock washer | 4 |
| 8 | Clamp bar | 1 |
| 9 | Clamp adjusting nut and spacer | 4 |
| | ***Counterweight Assembly Parts*** | |
| 12 | Left counterweight shaft (short) | 1 |
| 13 | Right counterweight shaft (long) | 1 |
| 41 | Counterweight shaft bearing | 4 |
| 42 | Counterweight shaft bearing mounting screw & lock washer | 8 |
| 14 | Counterweight | 4 |
| 43 | Counterweight clamp bracket | 4 |
| 44 | Counterweight clamp bracket bolt & lock washer | 8 |
| 15 | Counterweight shaft pulley & set screw | 2 |
| 16 | Timing belt | 1 |
| 17 | Idler bracket | 1 |
| 45 | Idler bracket mounting screw with lock & flat washers | 2 |
| 46 | Idler bracket adjusting screw with locking nut | 1 |
| 18 | Idler pulley mounting screw & lock washer | 1 |
| 19/62 | Idler pulley with bearing set | 1 |
| | ***Drive Shaft Assembly Parts*** | |
| 20 | Drive shaft with eccentric, set screw, and roll pin | 1 |
| 47 | Drive shaft bearing | 2 |
| 42 | Drive shaft bearing mounting screw & lock washer | 4 |
| 49 | Timing pulley & set screw | 1 |
| 21 | Drive pulley with set screw | 1 |
| 22 | Drive belt | 1 |

| | PARTS | NO. REQUIRED |
|---|---|---|
| | ***Connecting Rod Assembly Parts*** | |
| 50 | Connecting rod with grease fitting | 1 |
| 51 | Connecting rod rubber bushing | 1 |
| 52 | Connecting rod bearing with inner race | 1 |
| — | (Connecting rod assembly - Parts 50, 51, 52, assembled) | (1) |
| 24 | Connecting rod mounting bolt with lock nut | 1 |
| 54 | Connecting rod mounting bolt spacer | 2 |
| | ***Lower Guide Bearing Assembly Parts*** | |
| 59 | Lower guide bearing housing with guide bushing | 1 |
| 56 | Lower guide bearing mounting screw & lock washer | 2 |
| 26 | Lower guide bearing pin | 1 |
| 64 | Lower guide bearing pin clamp bolt with lock nut | 1 |
| | ***Electric & Drive Parts*** | |
| 63 | Motor, 1/4 hp, 115V, 60Hz, 1Ph, 1725 RPM | 1 |
| 60 | Motor Pulley & set screw | 1 |
| 61 | Motor mounting bolt with lock & flat washer | 4 |
| — | Electric cord assembly, motor-to-timer | 1 |
| — | Electric cord assembly, with ground plug | 1 |
| — | Electric cord grip grommet | 1 |
| | Timer, Digital (EDA) | 1 |
| | Timer, Digital (Artisan) | 1 |

## Replacement Trays and Wire Cloth

Porta-Screen® Tray, complete with wire cloth

| Model | |
|---|---|
| PSA-300 | 2" to No. 4 inclusive |
| PSA-301 | No. 5 to No. 14 inclusive |
| PSA-302 | No. 16 to No. 80 inclusive with wire cloth supports |
| PSA-302 | No. 100, with backup cloth |
| PSA-306 | No. 200, with backup cloth |
| PSA-310 | Dustpan tray |

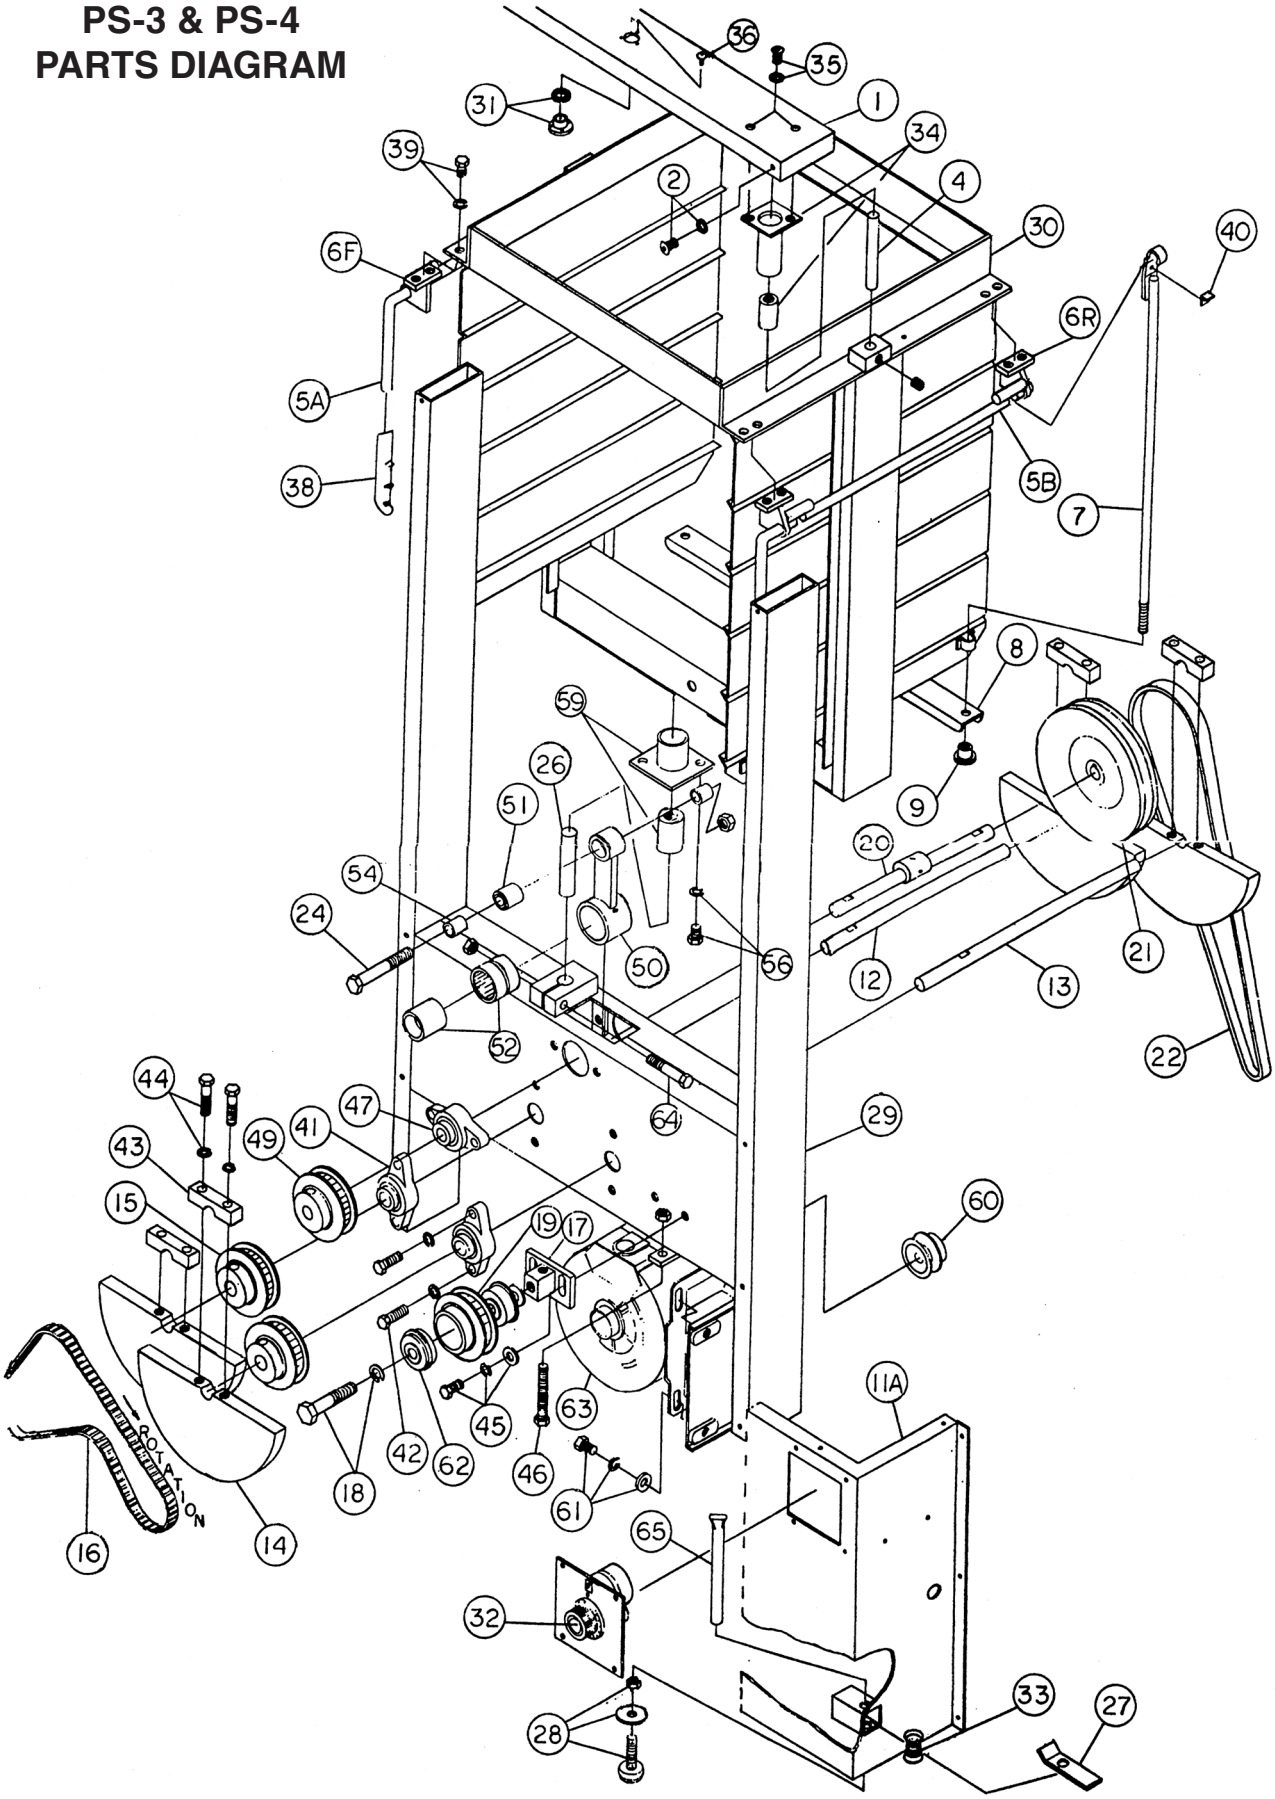
Replacement Wire Cloth, complete with metal shields & resilient gasket backing

| Model | |
|---|---|
| PSA-325 | 2" to No. 4 inclusive |
| PSA-326A | No. 5 to No. 14 inclusive |
| PSA-326B | No. 16 to No. 100 inclusive |
| PSA-327 | No. 200 |
| PSA-225 | Backup cloth (use with No. 100 to No. 200) |

Screen Tray Parts

| Model | |
|---|---|
| PSA-336 | Tray, complete, but without wire cloth, supports, or backup cloth |
| | Tray side clamp (4 required per tray) |
| | Tray bolts & nuts (12 required per tray) |
| | Wire cloth support (3 required per tray) |

# PS-3 & PS-4
# PARTS DIAGRAM



## 6.0 Accessories

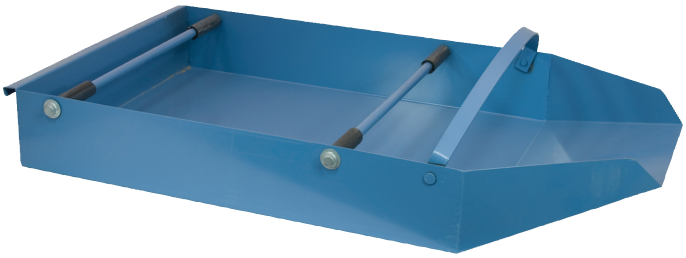
**Porta-Screen® has Foot-Tab leveling.**

**Porta-Screen® Tray cloth has metal shields to eliminate partial openings.**

**PSA-114 Porta Wheels** may be attached for added mobility. Ball-bearing wheel assemblies with rubber tires are predrilled for quick attachment to frame of Porta-Screen®.

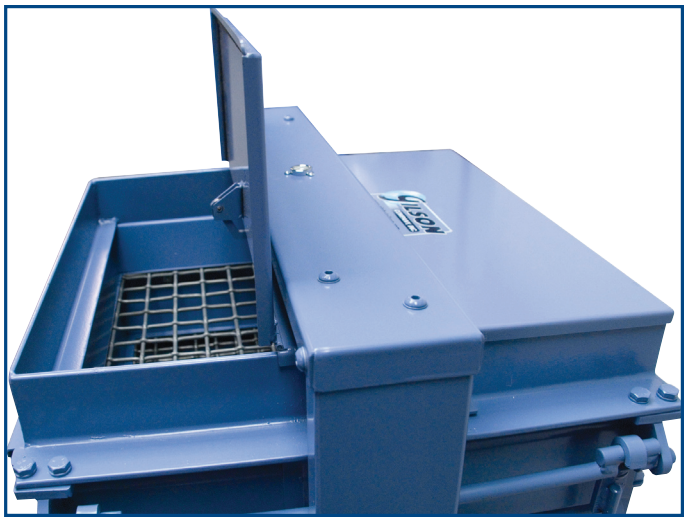
**PSA-114**

**PSA-367 Porta-Pan** is helpful in emptying and cleaning trays and in weighing operations. This 17x30x4in (432x762x102mm), WxLxD chute-end pan is sized to fit inverted trays and hold entire samples for cumulative weighing. Handling is easy with the top swing-away handle and end handle grip.



**PSA-367**

**PSA-312 Porta Cover** bolts to the top flange to enclose the sample chamber. It has a latch, and is hinged to open for introduction of samples.



**PSA-312 on PS-3**

Project Operating Procedure

# Operation of the TSI Model 8520 DustTrak™ Aerosol Monitor

## 1.0 Scope and Applicability

**1.1** This Project Operating Procedure (POP) defines the procedures for monitoring particulate matter (PM) using a totally portable system.

**1.2** This POP is to be utilized to conduct the work identified in the title of this POP. Refer to SOP 1011, Preparation and Control of Standard Operating Procedures, for SOP modification and Project Operating Procedure (POP) development procedures.

## 2.0 Health and Safety Considerations

**2.1** The health and safety considerations for the work associated with this POP, including both potential physical and chemical hazards, as well as personal protective equipment (PPE) requirements, will be addressed in the site specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager Interferences.

## 3.0 Interfaces

**3.1** The following may cause errors in data that could cause erroneous operation of this system:

- If the analyzers are in need of maintenance or repair;
- If environmental conditions are beyond the limits specified in the instrument manual;
- Excessive ambient moisture either because of high humidity or precipitation will interfere with the proper operation of either instrument; and
- Operation of the system in portable mode without a fully charged battery can interfere with the proper measurement of PM data.

## 4.0 Equipment and Materials

**4.1** The following equipment and materials are required for operation of the PAM station:

- Trimpot screw driver;
- Flow meter with a measurement range of 0-3 LPM;
- Zero particulate filter; and
- Operator manuals for TSI model 8520 DustTrak™ aerosol monitor.

## 5.0 Procedures

**5.1** ON/OFF key

Press the ON/OFF key to power the DustTrak monitor. The DustTrak monitor immediately begins an internal self-check, while illuminating the display digits and symbols. If a problem is detected, the display shows the message "SERVICE" along with a number indicating that the DustTrak monitor requires service. Refer to Chapter 5: "Troubleshooting," of the manual for information regarding service numbers. If the "SERVICE" message appears, the DustTrak monitor will pause until any key is pressed. (**NOTE**: when the cause of the service message is resolved, the message must be reset according to instructions specified in the user manual, if not, the message will re-appear again each time the DustTrak is powered on.)

**5.2** Manually Setting the Real-Time Clock

To set the time and date with the keypad, you must press and hold the SAMPLE key while the DustTrak monitor displays the current time. Hold the SAMPLE key until the monitor "beeps". You will have an opportunity to view and/or change the year, month, and calendar day, hours, and minutes in sequence.

Use the up and down arrow keys (↓ ↑) to change a setting. Use the SAMPLE key to store each setting and advance to the next one. (**NOTE**: it is imperative to set the correct time and date when operating in the data logging mode.)

**5.3** SAMPLE Key

Press the SAMPLE key to start/stop data sampling. The word "SAMPLE" appears in the upper right corner of the display while the DUSTTRAK monitor is in sample mode. When sampling is stopped, the DustTrak monitor automatically scrolls through statistics for the sampling period that just ended. (**NOTE**: Data sampling must be stopped in order to establish communication with TrakPro software to download logged data.)

**5.4** TIME CONSTANT Key

Momentarily press and release the TIME CONSTANT key to view the current time-constant. To change the time-constant, press and hold the key down. The available time-constant choices will scroll on the display. When the desired value is displayed, immediately release the key. Select 10 seconds as the time constant for standard operation.

**5.5** SAMPLING MODE Key

The SAMPLING MODE key allows you to select among the four (4) sampling modes: Survey, LOG 1, LOG 2, and LOG 3. Each time you press the SAMPLING MODE key, the DustTrak monitor sequences to the next mode. When the DustTrak monitor is in Survey mode, the current measurement will be shown on the display. When one of the LOG modes is selected,

the LOG mode number, (i.e., LOG 1, LOG 2, or LOG 3) will be displayed along with the percentage of free memory available.

**5.6** Survey Mode

When the DustTrak monitor is first turned on, it will always be in Survey mode. Survey mode allows you to make real-time measurements of aerosol concentrations, and to obtain statistics for that sample. The statistics include the average, minimum, and maximum values, as well as the elapsed time for that sample. Individual data points are not recorded in internal memory (this can be done in any of the LOG modes). Each new sample taken in Survey mode clears the previous sample data from memory. Data taken in Survey mode remains in memory until another sample is made, or until samples are taken in one of the LOG modes. Turning the DustTrak monitor off will ***not*** erase data.

Use the SAMPLE key to start and stop a sample

**5.7** LOG Modes

There are three (3) LOG modes: LOG 1, LOG 2, and LOG 3. When one of these modes is selected using the SAMPLING MODE key, the LOG mode number will be listed at the top of the display. The LOG modes allow you to record aerosol concentration data points in the internal memory for later retrieval and analysis using the TraKPro software provided with the instrument. Use the SAMPLE key to start and stop recording. The word “RECORDING” appears at the top of the display when recording is in progress. The frequency that data is recorded can be set for LOG 1 mode with the LOGGING INTERVAL key. (**NOTE**: the logging interval is also the data averaging time used by the DustTrak and only block average can be generated.) Use TraKPro software for LOG 2 and LOG 3 modes. (**NOTE**: LOG2 and 3 are for timed or scheduled on/off sampling.)

Data recorded using one of the LOG modes can only be erased by using the CLEAR MEMORY key. Turning the DustTrak monitor off ***will not*** erase data. Recording another sample (by turning sampling off and on again) with one of the LOG modes without clearing memory first will cause new data to be added to the existing data in the memory and these new data will be identified with a new TEST number.

**5.8** LOGGING INTERVAL key

This key sets the frequency and averaging period for LOG1 mode. Use SAMPLE MODE key to set the monitor to LOG1 mode, press and hold the LOGGING INTERVAL key, release this key when the desired interval is displayed. (**NOTE**: Only TraKPro software can be used to set interval for LOG 2 and 3.)

**5.9** CLEAR MEMORY Key

Use the CLEAR MEMORY key to erase stored data. The CLEAR MEMORY key ***will not*** respond unless the DustTrak monitor is in one of the three LOG modes. (**NOTE**: before

clearing the memory, you should first download the data to a computer through the TraKPro software.

***There is only one block of memory in the DustTrak monitor. Clearing the memory for one LOG mode clears memory for all LOG modes.***

To clear the memory, press and hold the CLEAR MEMORY key until the countdown reaches zero, then release quickly. This prevents the data from being accidentally erased. Releasing the key too soon or too late prevents memory from being cleared. (**NOTE**: the DustTrak monitor has memory capacity of 31,000 data points, if the data average interval is set to 15-minutes, it could store data up to a total of 322 days. After the memory is cleared 100% memory should be displayed.

**5.10** The Arrow Keys 

The two arrow keys are used to adjust the readings when calibrating the DustTrak monitor and for adjusting the time and date for the internal real-time clock.

**5.11** CALIBRATE Key

Use the CALIBRATE key to put the DustTrak monitor into calibration mode. See Chapter 4, “Maintenance” and Step 5.1.12 below for details on how to perform zero calibration of the monitor.

**5.12** Display/Keypad Lockout Switch

Recording data over extended time periods often requires leaving the DustTrak monitor unattended. To reduce the risk of having an unauthorized person either intentionally or inadvertently interrupt the measurements, you can lock the display and keypad. The lockout switch is on the backside of the DustTrak monitor between the data port and the external power socket. It is a small slide switch and is recessed so that a pointed device must be used to move it.

- With the switch in the right side position (nearest the power socket), the keypad and display functions will work normally.
- With the switch in the left side position (closest to the data port), the display and keypad will go into lockout mode.

There are two ways to use the lockout switch.

1. Lock the keypad after recording starts, or
2. Put the switch into the lockout position prior to when recording starts.

The second method will enable you to operate each function normally *until* the SAMPLE key is pressed in one of the LOG modes. At that time the keypad automatically locks. When the display and keypad are locked, the display shows the words “RECORDING LOG X ” where “X” is the current LOG mode number.

**5.13** Zero Checking/Re-Zeroing/Calibration

To calibrate or perform a zero check on the DustTrak, use the following steps:

1. Put the DustTrak monitor in Survey mode;
2. Connect zero particulate filter (supplied by DustTrak manufacturer) on monitor sample inlet. (See Figure 4–1 of the manual for an illustration on how to make the connection);
3. Set the time-constant to 10 seconds, if necessary. Press and hold the TIME CONSTANT key until “10” is displayed, then release;
4. Wait 10–60 seconds for displayed values to settle to zero;
5. If the displayed value is between -0.001 and +0.001 mg/$m^3$, the DustTrak monitor does not need adjustment. If the displayed value exceeds this limit, follow steps 6 to 8 below to re-zero the instrument;
6. Press and hold the CALIBRATE key and wait for the displayed countdown to reach 0, then immediately release the key. The message “CALIBRATE ZERO” is displayed. If it is not displayed, try again;
7. Press the SAMPLE key and wait for the 60-second countdown. When the countdown is completed, the current calibration constant will be displayed; and
8. Press the CALIBRATE key again to return to survey mode. The re-zeroing process is now completed.

**5.14** Verification/Adjustment of sampling flow rate

The standard sampling flow rate for the DustTrak 8520 is 1.7 LPM and should be verified and adjusted initially and on a regular basis. The particle size cut-off is based on this flow rate for each size cut-off nozzles and cyclone.

Connect the flowmeter (supplied by manufacturer) to the monitor sample inlet, hold the flowmeter in a vertical position (as illustrated on Figure 4-4 of the manual) and verify the flowmeter ball height (middle of the ball) is at 1.7 LPM. If necessary, adjust the flow adjustment trimpot with a small screw driver until the flow rate is at 1.7 LPM. The flow adjustment trimpot is located at the back panel of the DustTrak monitor.

**5.15** Maintenance

(See Chapter 4 of the Operation Manual for recommended maintenance schedule and detailed maintenance procedures)

**5.16** Standard Startup Procedure for DustTrak 8520

Standard Startup procedure is as follows for the DustTrak:

5.16.1 Instrument set up

- Power up - press ON/OFF key
  - DustTrak should begins self-check sequence ,and display all digits and symbols;
  - Verify no SERVICE messages; and
  - Verify adequate battery life remaining and no battery symbol is displayed.

- Verify internal clock - adjust clock if necessary either manually or through the use of TRAKPRO Software

- Verify flow rate @ 1.7 LPM_– connect rotameter to inlet nozzle, check and verify ball high (mid-ball) at 1.7 LPM, adjust flow pot if necessary

- Verify time constant (recommended to use 10 seconds)

- Verify or Select/sampling particle size inlet. The selections are as follow:
  - 4.0 um: install BLACK nozzle and CYCLONE;
  - 10 um: install BLACK nozzle;
  - 2.5 um: install BLUE 2.5 um nozzle with impactor plate and O-ring; and
  - 1.0 um: install BLUE 1.0 um nozzle with impactor plate and O-ring.

- Zero checking/re-zeroing **-** perform this procedure:
  - Daily from cold start;
  - Ambient temperature change exceeds more than 8C;
  - Maintenance is performed; and
  - DustTrak is moved from high aerosol concentration to a low concentration location.

- Put DustTrak in SURVEY mode (press SAMPLE key if need to).

- Connect filter to inlet nozzle.

- Press and hold TIME CONSTANT key to verify display is in 10 sec (00:10:00).

- Wait 10-60 second sampling, readings should be approaching zero.

- If stable reading is between +/- 0.001 mg/$m^3$, no zeroing will be needed.

- If reading exceeds this limit, press and hold CALIBRATE key until count down to 0 and release key immediately, "CALIBRATE ZERO" message should be displayed, if not try again.

- Press SAMPLE key to initiate the 60 seconds countdown. Current calibration factor should be displayed after the countdown.

- Press CALIBRATE key to return DustTrak to survey mode and zeroing is completed.

5.16.2 Set DustTrak in one of the four SAMPLING MODEs

- Survey mode – default mode after power up : to display real-time readings ( no internal logging) – this mode is use mostly for analog output to connect to an external data logger.

- LOG 1 – sample and record average readings in internal memory
  - Press SAMPLE MODE until LOG1 is displayed;
  - Press LOGGING INTERVAL to verify averaging period (e.g., 15 minute);
  - Or press and hold key until the desired interval is displayed, release key immediately; and
  - Press SAMPLE key to start sampling. In additional to readings, **LOG1 Recording and Sample** message will also be displayed, this verifies that sampling is in progress and data averages will be stored in internal memory.

**NOTE**: each time when SAMPLE key is pressed to stop and start a new sampling event, a new test ID will be created for the current sampling event).

- LOG2 and LOG3 – user selectable auto start/stop operation and average readings recorded in internal memory.

5.16.3 Enable Alarm (only through the use of TraKPro software)

- Start up TraKPro.
  - Select Instrument Setup, select Parameters, Alarm Setpoint;
  - Check Alarm Enabled box;
  - Enter an alarm limit (e.g., 0.150 mg/$m^3$);
  - Press send button to program the DustTrak;
  - When alarm is triggered, internal beeper will be on once/second and AL message will be flashing on display; and
  - Alarm will be turned off when reading falls below 5% of limit.

5.16.4 If LOG1 mode is used, verify and/or select the LOGGING INTERVAL. Verify adequate memory is available.

5.16.5 Verify no battery warning is displayed. Press SAMPLE key to start the sampling session. (**NOTE**: SAMPLE should be displayed on the top right hand corner of the display panel).

**5.17** Use of TraKPro Software

TraKPro is a companion software designed to assist in the operation of DustTrak 8520. TraKPro provides a number of operation features that cannot be initiated through the keypad.. These features include the following:

- Logging Interval for LOG2 and 3;
- Enable/disable data alarm and setting/modifying alarm threshold;
- Setting up analog output range;
- Downloading and exporting logged data; and
- Generating data reports.

5.17.1 Follow the procedure described in Chapter 2 “Setting up TraKPro Data Analysis Software” to connect the monitor to a Personal Computer (PC).

**NOTE**: Sampling must be stopped manually (press the SAMPLE key) in order to establish communications between the monitor and PC.

5.17.2 Follow the procedures described in Chapter 3 “Analog Output”; “Alarm Output Specifications and Programming the Alarm Set Point”; and “Programming Advanced Modes: LOG2 and LOG3” to configure the monitor as needed.

**NOTE**: DustTrak 8520 will alarm only on instantaneous readings.

5.17.3 Downloading and Exporting logged data

1. Open TraKPro Software.
2. Click on File in the TraKPro task bar.
3. Select Receive.
4. On the sub-menu “Logged data Test(s) to receive”, sampling events stored in monitor (identify by Test ID number, Test date and time) will be listed on a menu. You either Select ALL or highlight the test ID to select the data you want to transfer from the DustTrak to the PC, and then click Receive…
5. After the data transfer is complete, a confirmed window “Logged Test(s)” will open with more detailed information on the selected test ID. By highlighting the Notes at the end of each test ID, the operator can add specific comments associated with each test ID (i.e., test location or site code before it is saved).

6. Click File, select Save As, select a file destination, specify a file name, and click Save. The data will be saved with a TPK extension (the TrakPro native file).
7. To export data as text file that can be used with MS Excel, click File, select Export, and select Export Test Data. At this point a window will come up listing the test IDs, start date, and time.

**NOTE**: The default Data Delimiter is Comma.

**M**odify the selection as needed, highlight the monitoring event(s) to convert, click Export, specify a file destination, specify file name, and click Save. A text file with a .TXT extension will be created and saved.

**NOTE**: a standard file naming convention is recommended, at a minimum the name should contain information to identify the site location and date of sampling, an example is as follows:

**NNNN mmddyy** where:

NNNN = site code or location

mm = month

dd = day

yy = year

## 6.0 Quality assurance / quality control

**6.1** Calibrations must always leave the analyzer operating within ± 5.0% of the reference calibrator at each calibration input.

**6.2** As soon as possible following calibration, the completed data form is to be submitted to the project manager or designee for review. Standards are reviewed for traceability and completeness. Data and strip chart readings (where applicable) are to be reviewed for agreement and completeness

## 7.0 Data and records management

**7.1** Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records.

**7.2** Records associated with the activities described in this POP will be maintained according to the document management policy for the project.

7.2.1 The field documentation (PAM Station Checklist) is included at the end of this POP.

**7.3** Completed calibration data sheets are subject to senior review in accordance with AECOM senior review policy (SOP 1003, Senior Review). Calculations, standard conditions, correction factors, project identification, and other data will be reviewed for accuracy, completeness and conformance to the relevant AECOM operational SOP and the project QA Plan.

## 8.0 Personnel Qualifications and Training

**8.1** Qualifications and training

8.1.1 The individual executing these procedures must have read, and be familiar with, the requirements of this POP.

**8.2** Responsibilities

8.2.1 The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

8.2.2 The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

Standard Operating Procedure

# Calibration/Operation/Maintenance of MiniVol™ Tactical Air Sampler (TAS)

## 1.0 Scope and applicability

**1.1** This Standard Operating Procedure (SOP) provides the guidance for the use of the MiniVol™ Tactical Air Sampler (TAS), to provide a standardized procedure for the collection of particulates or vapors.

**1.2** This sampler may be used to collect particulate matter on various types of filer media or gases/vapors in Tedlar™bags. General sampler calibration procedures are given in ENSR SOP 2000-106.

**1.3** This SOP is to be utilized to conduct the work identified in the title of this SOP. In the event the Project Manager or Project Team determines that the protocols and procedures listed in this SOP are not applicable to the project, there is the option to either adapt this SOP or to develop a site-specific SOP to more closely match the requirements of the project. Refer to SOP 1011, Preparation and Control of Standard Operating Procedures, for SOP modification and Project Operating Procedure (POP) development procedures.

## 2.0 Health and safety considerations

**2.1** The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, as well as personal protective equipment (PPE) requirements, will be addressed in the site specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

**3.1** Physical disturbance of the sample during collection can result in significant loss of sample. Care must be taken to minimize disturbance of samples during collection to ensure that intact discrete samples are obtained and that the samples are representative of the intended interval.

**3.2** Communication with the laboratory in the project planning stages is critical to address the potential issues that may arise.

## 4.0 Equipment and materials

A standard MiniVol™ TAS comes packed in an all weather carrying case containing the following:

- 1 MiniVol™ TAS Pump Module
- 2 Filter Holder Assemblies
- 2 Size Selective Impactors
- 2 Battery Packs and a Battery Charger

- 1 All Weather Carrying Case
- 1 Universal Mounting Bracket or Light Weight Tripod

During particulate matter sampling, the following consumables are needed for proper operation of the MiniVol™TAS:

- Impactor grease - Glisseal® Ht, Apiezon® M Grease, etc.
- 47 mm filters - pure quartz, pure Teflon®, Teflon®-coated glass, etc.
- Petrislides™ - for storage and transport of the filters.
- A microbalance accurate to one microgram is needed to weigh the filters.
- Operation Manual.
- ENSR SOP 2000-106 Ambient Monitoring Transfer Standard Calibration.

# 5.0 Procedures

**5.1** Charging batteries

1. Connect the charging plug of the battery charger to the charging jack on the battery pack.

2. Plug the charger into an AC outlet.

3. The LED on the top of the battery charger will light indicating the status of the battery being charged.

When this light is green the battery is charged. A fully discharged battery requires about 5 hours to be completely recharged.

**Battery Charger LED Status Modes**

**LED Status Battery Status**

- Green Battery Fully Charged
- Red Battery Partially Charged
- Flashing Red Battery Fully Discharged

**5.2** Turning the sampler On/Off

The ON/AUTO/OFF button on the Programmable Timer allows the operator to manually turn the sampler on or off (or to place it in the "Auto" mode in which it is controlled by programmed on/off sequences). As the ON/AUTO/OFF button is pressed, a bar at the lower edge of the LCD display moves horizontally over the words "On", "Auto" and "Off" which are printed on the timer case. With the battery pack inserted into the sampler, press the ON/AUTO/OFF button until the bar is above

the "ON" legend. The red power indicator (to the right of the ON/AUTO/OFF button) should light and the pump motor should start. If the timer display does not respond, press the small black reset button located next to the red power led. While the sampler is running press the ON/AUTO/OFF button, until the bar indicator is over the “OFF” legend. The power indicator light will go off and the pump will stop running.

**5.3** Programming the timer

The Programmable Timer can be set to run up to six on/off cycles within a 24 hour period, as well as to run for separate time periods on separate days within a 7-day period. To set the timer, first set the real-time clock to establish the correct time frame in which the cycles are to run. Next, enter the on/off times at which the programmed cycles are to begin and end. Finally, set the timer to "Auto" mode.

**5.4** Setting the real-time clock

1. DAY SET: Hold down the CLOCK button and press the WEEK button until the correct day appears at the top of the display.

2. TIME SET (Hour): Hold down the CLOCK button and press the HOUR button until the display indicates the correct hour. You may have to cycle through the hours twice to obtain the proper AM or PM (on the left side of the display). Seconds will automatically reset to zero.

3. TIME SET (Minutes): Hold down the CLOCK button and press the MIN button until the display indicates the correct minutes. Seconds will automatically reset to zero.

**5.5** Setting the On/Off times

1. Press the **PROG** button once. **1ON** will appear near the lower left corner of the display indicating that the Power-on time for the first cycle is ready to be programmed.

2. Press the **HOUR** and **MIN** buttons to enter the power-on time for the first cycle.

3. Press the **WEEK** button to select the desired day. The days appear along the top of the display. Continuously pressing the **WEEK** button will sequentially display "Mo Tu We Th Fr Sa Su", "Mo", "Tu", "We", "Th", "Fr", "Sa", "Su", "Mo Tu We Th Fr", "Sa Su" and finally back to "Mo Tu We Th Fr Sa Su".

   **NOTE: When more than one day is displayed, these days will all have the same power-on time.**

4. After you have entered the power-on time and date for the first cycle, press the **PROG** button. **1OFF** now appears on the display to indicate that the power-off time for the first cycle is ready to be programmed. Repeat steps 2 and 3 to enter the desired power-off time.

   **NOTE: The power-off time does not have to occur on the same day as the on time. In this way, sampling may start on one day and end on the next day**.

5. Press the **PROG** button again. **2ON** appears on the display to indicate that the second power-on time is ready to be programmed. Repeat steps 2 through 4 to enter the remaining power-on/power-off times (up to 6 on/off times).

6. Press the **PROG** button to step through the times you entered to make sure they are correct. Press the **RST/RCL** button to disable (ReSeT) or reactivate (ReCalL) any time entries. When you disable a particular power-on/off entry, four dashes will appear instead of the time. When you reactivate an entry, it will return to the values that were set before you performed a reset.

   **NOTE: Be sure to clear or reset all unwanted time entries prior to sampling in the AUTO mode. Both ON and OFF entries need to be disabled for the unwanted programs to be inactive.**

8. Press the **CLOCK** button to return to the real-time clock display.

9. Press the **ON/AUTO/OFF** button until the bar is positioned above the desired setting (see below).

**5.5.1** Setting the time to “ON,” “AUTO,” and “OFF” modes

The **ON/AUTO/OFF** button is used to manually turn the sampler on or off, or to place it in the "Auto" mode. A bar on the lower edge of the LCD display moves from "Off" to "Auto" to "On" as the button is pressed. In the "Auto" mode the sampler is controlled by the programmed on/off sequences.

To manually turn the sampler ON, press the ON/AUTO/OFF button until the bar on the lower edge of the display is above the "ON" legend. The pump will start and the power indicator will light.

To manually turn the sampler OFF, press the ON/AUTO/OFF button until the bar is above the "OFF" legend.

To set the timer to "AUTO" mode, in which the sampler will be automatically controlled by programmed sequences, first turn the sampler OFF. Then press the ON/AUTO/OFF button until the bar is above the "AUTO" legend.

**5.6** Checking for leaks

To check for leaks, remove the impactor/filter holder assembly from the inlet tube. Make sure that the inlet tube is fully extended and the compression fitting is tight. Cover the air inlet tube with the

palm of the hand while the pump is running. The ball in the flowmeter should drop to zero and remain there without movement.

**NOTE: If the "Low Flow" indicator LED activates and the sampler shuts down after 15-20 seconds, push the reset button twice to reactivate the sampler. If the ball does not drop to zero, a leak exists somewhere in the hoses and/or fittings between the inlet and the flowmeter.**

Leaks on the inlet side of the pump are especially critical, since flow measurement will not accurately reflect the amount of air passing through the filter. The sampler will be measuring air passing through the filter, plus whatever air may be entering through the leak.

If there is a leak use the following procedures to isolate the leak. After each procedure check the sampler for leaks before moving to the next step:

- Verify that the inlet tube is extended and the compression fitting is tight.
- Remove the four faceplate thumbscrews and the sampler mount thumbscrew to access the sampler pump and plumbing.
- Verify that all push-on hose fittings are secure.
- Check for cracks in the flowmeter inlet and outlet.
- Check for cracks in the pulse dampener.
- Check and tighten all compression fittings.

**5.7** Particulate matter sampling

Sampling procedures for TSP, $PM_{10}$, and $PM_{2.5}$ are identical except for the configuration of the impactor/filter holder assembly.

**5.7.1** Preparing the sampler

**TSP** - Remove the impactor from the filter holder assembly prior to sampling. Since the impactor will not be used, greasing and cleaning of the impactor's target disk need not be done.

**$PM_{10}$** - Use a $PM_{10}$ impactor in the filter holder assembly. Greasing and cleaning of the impactor's target disk should be performed initially and after every fifth sample (or more often if heavy loading is observed).

**$PM_{2.5}$** - Use a $PM_{2.5}$ impactor in the filter holder assembly and a $PM_{10}$ impactor in a multiple impactor adapter mounted on the filter holder assembly tube. Greasing and cleaning of the impactors' target disks should be performed initially and after every fifth sample (or more often if heavy loading is observed).

To remove impactor, use your thumb to simply push the impactor out of its tube from bottom to top. When correctly installed, the impactor's top is flush with the surrounding filter holder assembly tube or multiple impactor adapter tube.

Before transporting the MiniVol™ TAS to the field, perform a laboratory check to determine if it is operational.

- Turn the sampler on and observe the motor performance.
- Perform a leak check. Investigate and correct any malfunctions before proceeding.
- Perform a single-point flow rate check using a calibrated orifice, soap-bubble meter or other flow measuring device of known accuracy and compare to the curve established during calibration. The flow should be within ±10% of 5 LPM at current conditions. If the unit fails to operate in this range, check the sampler for obvious leaks and malfunctions. The sampler must be repaired or recalibrated if the flow criteria are not met.

**5.7.2** Flow rate

The particle size cut point of the impactor is a function of the velocity with which the air stream passes through the impactor and impacts on the target. The impactor is designed to have the correct cut point at an air flow rate of 5 LPM at ambient conditions. Since the density of air and the behavior of the flowmeter are functions of the ambient air temperature and atmospheric pressure, a flow rate set point must be calculated for each different sampling project.

The sampler air flow calibration curves that are supplied with each sampler contain the necessary information needed to determine the flowmeter set point for a particular ambient condition.

Flowmeter calibration

The sampler should be recalibrated once a year and/or if the flowmeter is replaced (see ENSR SOP 2000-106 Ambient Monitoring Transfer Standard Calibration.

**5.7.3** Particulate matter sampling procedure

After the sampler has been assembled (refer to sections 4.7-4.14 of the MinVol ™ manual), adjusted, verified to be in proper working order, and a filter loaded in the Filter Assembly, the sampler is ready to collect air samples.

1. Carefully transport the sampler to the field site. Verify that the sampler, when finally installed will be positioned with the intake upward in an unobstructed area at least 30 cm from any obstacle to airflow.
2. Place the sampler on a firm level surface.
3. Loosen the inlet tube compression nut and extend the inlet tube to the maximum height and re-tighten the nut. Check for leaks.
4. Remove the clean Impactor/Filter Holder Assembly from the plastic transport bag or case. Attach the assembly to the top of the sampler inlet tube.
5. Record the following information on the PM Field Data Sheet: Site ID, number of the filter, the battery ID, sampler ID, ambient temperature and pressure, flowmeter

reading, and elapsed time meter reading. (a copy of the data sheet may be downloaded from the Airmetrics website, www.airmetrics.com).

6. Open the sampler case and obtain the beginning flow rate, press the **ON/AUTO/OFF** button to start the pump. On the LCD display, the horizontal bar should move to "ON".
7. If the flowmeter, which should be in the vertical position, indicates zero or a very low reading, check for restrictions.
8. Using the Flow Rate Adjustment control, set the flowmeter within specifications for the project temperature and pressure conditions. Take the reading of the flowmeter from the center of the ball.
9. Press the **ON/AUTO/OFF** button twice to stop the pump.
10. Press the **ON/AUTO/OFF** button to set the timer to "Auto" mode.

    **NOTE: The Sampler MUST be in "Auto" mode before the operator leaves if the sampler is to run at a pre-programmed time.**
11. Close the sampler case.

### 5.7.4 Particulate matter sample retrieval

As soon as possible after the end of the sampling period, the operator should return to the monitoring site to retrieve the exposed filter. There is a potential for filter damage or changes in sample mass due to particle loss, passive deposition, or volatilization increases if the filter is left in the sampler for extended periods of time after the sampling activity has ceased. On the previously referenced Field Data Sheet record the ambient temperature (Ta), barometric pressure (Pa), flowmeter reading and elapsed time.

**NOTE: Ta and Pa readings may be estimated on site or may be obtained from a nearby US National Weather Service Forecast Office or airport weather station. Barometric pressure readings obtained from airports must be at station pressure (not corrected to sea level), and they may have to be corrected for differences between the elevation of the monitoring site and that of the airport. If Ta and Pa readings are not available, seasonal average temperature ($T_{avg}$) and barometric pressure ($P_{avg}$) may be substituted. Care must be taken that the actual conditions at the site can be reasonably represented by such averages. It is therefore recommended that seasonal values represent actual values within 20°C and 40 mmHg.**

1. Open the sampler case and check the sampler for any error conditions. Repair as needed.
2. Verify correct time and day of week on time LCD.
3. Record elapsed time as shown on the Elapsed Time Totalizer.
4. Obtain ending flow rate:
   - Press the **ON/AUTO/OFF** button to start the pump.

- With the flowmeter in a vertical position, record the flow rate to the nearest 0.25 LPM (read at center of ball).
- Press the **ON/AUTO/OFF** button twice to stop the pump.

5. Exchange a new impactor/filter holder assembly for the exposed filter holder assembly. Perform a crosscheck of the exposed filter number with the filter number recorded on the Field Data Sheet for the run just completed. Also, check the filter number against the site number.
6. Change the battery pack.
7. Obtain beginning flow rate (see above, step 4).
8. Make sure the timer is set for the desired period and in the **"AUTO"** mode.

**5.7.5** Exposed filter

1. In the laboratory, unscrew the filter holder and remove the filter cassette.
2. Locate the Petrislide™ with the filter number which matches the number on the side of the filter holder assembly. This is the original Petrislide™ in which the filter came.
3. Use the cassette separator (P/N 600-007) to remove the top half of the filter cassette.
4. Using forceps carefully remove the exposed filter from the filter cassette and place it into its original Petrislide™ with the exposed side of the filter facing up, replacing the Petrislide™ lid when finished.

   **NOTE: Be sure to replace the filter support screen in the filter cassette assembly.**
5. Remove the old ID tag from the filter holder assembly base and discard.

   **NOTE: Recheck this number to be sure it matches the number on the Petrislide™.**

**5.7.6** Maintenance

Ideally, records reflecting the history of maintenance (including all replacement parts, supplies, costs, expenditures) should be kept for each MiniVol™ TAS.

Check sheets should be used to record preventative and/or corrective maintenance activities and the subsequent sampler calibration curve.

The sampler is comprised of four basic components that require maintenance:

- impactor/filter holder assembly,
- flow control system,
- timer, and
- battery pack.

Section 6 of the MiniVol™ TAS Operation Manual details the recommended maintenance procedures.

# 6.0 Quality assurance / quality control

**6.1** Quality control requirements for the MiniVol™ TAS are dependent on project-specific objectives. The Quality Assurance Project Plan (QAPP) will provide requirements for sample preservation and holding times, container types, sample labeling, sample packaging and shipment, as well as requirements for the collection of various quality assurance samples such as trip blanks, field blanks, equipment blanks, MS/MSDs, and field duplicate samples.

**6.2** Siting Requirements

Siting recommendations in the operational manual conform to the U. S. Environmental Protection Agency requirements as stated in the U. S. Code of Federal Regulations (40 CFR part 58, Appendix E). When operating the sampler in locations under another jurisdiction, the operator should follow the appropriate guidelines.

The MiniVol™ TAS should be positioned with the intake upward and should be located in an unobstructed area at least 30 cm from any obstacle to air flow. Accessibility to the unit under all weather conditions, along with safety and security of the monitoring personnel and equipment, should be prime considerations.

Completed calibration data sheets are subject to senior review in accordance with AECOM's senior review policy. Calculations, standard conditions, correction factors, project identification, and other data will be reviewed for accuracy, completeness and conformance to the relevant AECOM operational SOP and the project QA Plan.

# 7.0 Data and records management

**7.1** Forms must be completed and delivered to the project manager for review. A copy of these forms must be maintained on site. All columns on these forms must be completed or marked N/A if they do not apply.

**7.2** All activities performed in shelter must be documented in the field station log including date, the time in and out, technician's initials and employee number, activities performed, time the instrument is taken off-line, time the instrument is put back on-line, calibration results as well as any other circumstances which may arise during the site visit.

**7.3** Unanticipated changes to the procedures or materials described in this SOP (deviations) will be appropriately documented in the project records.

**7.4** Records associated with the activities described in this SOP will be maintained according to the document management policy for the project.

# 8.0 Personnel qualifications and training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this SOP.

**8.1.2** Field technicians must have been trained to operate, maintain and calibrate this sampler and must be familiar with procedures for proper documentation of test data.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this SOP.

**8.2.2** The individual performing the work is responsible for implementing the procedures as described in this SOP and any project-specific work plans.

**8.2.3** The Project Manager is responsible for determining the methods that are appropriate to achieve the project objectives, and for supplying the necessary resources to meet those objectives.

**8.2.4** The field sampling team leader or task manager is responsible for ensuring that this procedure is followed in collecting the samples.

Standard Operating Procedure

# Sample Collection of Airborne Hexavalent Chromium using Airmetric MiniVol Tactical Air Sampler and OSHA Method ID 215 Version 2

## 1.0 Scope and applicability

This Standard Operating Procedure (SOP) defines the collection procedures of airborne hexavalent chromium in ambient air and/or work places using OSHA Method ID 215 Version 2 on a polyvinyl chloride (PVC) filter. Ambient air is drawn through a polystyrene cassette preloaded with a PVC filter and stainless steel back-up screen at a measured flow rate through the use of the Air Metric MiniVol Tactical Air Sampler (TAS). After sampling, the filters are extracted in an alkaline digestion solution and analyzed colorimetrically in the laboratory using the procedures described in OSHA Method ID-215 Version 2.

**1.1** This SOP is to be utilized to conduct the field sampling tasks identified in the title of this SOP. In the event the Project Manager or Project Team Members determine that the protocols and procedures listed in this SOP are not applicable to the project, there is the option to either adapt this SOP or to develop a site-specific SOP to more closely match the requirements of the project. Refer to SOP 1011, Preparation and Control of Standard Operating Procedures, for SOP modification and Project Operating Procedure (POP) development procedures.

## 2.0 Health and safety considerations

**2.1** The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, will be addressed in the site specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

**3.1** The two known interferences in ambient sampling could be low humidity and low concentration that might affect the ability of PVC filter to retain hexavalent chromium (Cr (VI)).

## 4.0 Equipment and materials

- Air Metrics MiniVol TAS (Tactical Air Sampler or equivalent) with related apparatus and Manufacturer's instruction manual
- Air Metric (or equivalent) NIST traceable flow standard kit for calibrating the MiniVol TAS Sampler
- Cr(VI) Field Sampling Event Data Sheets

- Chain-of-custody forms
- Two-piece polystyrene filter cassettes with back-up screen
- Cassettes shipping plastic mailer
- 47 mm PVC filters
- Teflon coated forceps
- Small Shipping cooler
- Blue Ice
- Ziploc bag
- Small Bubble wrap

# 5.0 Procedures

### 5.1 PVC Filter Cassette Assembly Preparation

**5.1.1** Using the Teflon coated forceps, place a 47 mm PVC filter on the stainless steel screen in the outlet side of the two-piece cassettes

**5.1.2** Replace the inlet side of the cassette and then compress the two pieces together to form the cassette assembly

**5.1.3** Verify that the PVC filter is facing the inlet of the cassette assembly

**5.1.4** Place the assembled filter cassette in a clean cassette holder (plastic mailer) to seal the filter cassette

**5.1.5** Assembling of the filter cassette may be performed in the laboratory or the field.

### 5.2 Flow Calibration of the MiniVol TAS

The sample flow rate specified in OSHA Method ID 215 Version 2 is 2 liters per minute (LPM) and the total sample volume required is approximately 960 liters.

**5.2.1** In order to simulate the pressure drop that will be encountered during actual sampling, the PVC filter cassette assembly prepared in section 5.1 should be used in the flow calibration. It is advisable to dedicate a "dummy" cassette assembly for the purpose of calibrations and flow checks.

**5.2.2** Load the “dummy “ cassette assembly in the MinVol TAS filter holder . Remove the weather cap and insert the Air Metric flow calibration kit adaptor and connect the port of the adaptor to the digital manometer with suitable flexible tubing.

**5.2.3** The MiniVol TAS consists of an active constant flow device which compensates for changes in pressure drop across the sample train. The use of a dummy filter cassette assembly in-line during calibration and flow check serves as a verification that the pressure drop over the filter cassette assembly is not too great for the pump and is an exact duplication of conditions the pump will experience during sampling.

**5.2.4** For the operating procedures of the MiniVOl TAS and the Air Metric calibration kit, refer to the manufacturer instruction manual as well as its SOP

**5.2.5** Turn ON the MinVol TAS and digital manometer of the flow standard, and let it running and warm-up for at least 2-3 minutes, verify the ball height on the rotameter is at approximately 2 LPM, adjust the flow control circuit on the TAS until the ball height is at 2 LPM if necessary

**5.2.6** Measure the approximate flow rate through the calibration system train. Adjust the flow on the MiniVol TAS until the desired flow rate close to 3.5 LPM is achieved. Ensure to allow 10 to 15 seconds after each adjustment for the flow control mechanism to respond before activating the flow standard to take any flow measurement. Record the digital manometer reading of the adapter and the equivalent rotameter reading (midpoint of the ball) on the calibration data sheet. Record the ambient temperature and pressure, the standard pressure and temperature

**5.2.7** Repeat 5.2.7 for target flow rate of 3.0, 3.5. 4.0, 4.5 and 5.0 LPM

**5.2.8** Calculate the actual flow from each manometer reading from the equation provided with the calibration kit ( adaptor) for each ball height. Determine the relationship by linear regression or on a graph between the actual measured flow rates ( on Y axis) and the square root of equivalent rotameter reading( on X axis) corrected to actual temperature and pressure

**5.2.9** Determine the equivalent ball height (corrected to seasonal temperature and pressure ) of the rotameter for the sampling flow of 2 LPM

**5.2.10** When the calibration has been completed, remove the dummy filter cassette assembly and save it for future calibrations.

**5.3** Calibrate each MiniVol TAS following step 5.2 of this SOP.

**5.4** Record all calibration data on a Calibration Data Sheet including serial numbers as well as the calibrated flow rates, ball heights, temperature and pressure as well as flow rate vs. ball height relationship associated with each MiniVol TAS,

**5.5** Determine and record the seasonal, operation ball height as in step 5.2.10 for each MiniVol TAS.

**5.6** Install the MiniVol TAS consisting of a pre-loaded PVC filter cassette assembly at the sampling location. The height of the sample inlet should be approximately 2 meters from the ground. .

**5.7** Record all initial pertinent data on the Cr (VI) Field Sampling Event Data Sheet including sample location name, date of sampling, filter and cassette ID #, MiniVol TAS serial #, seasonal rotameter ball height, and start time on the elapsed timer.

**5.8** At the start of the sampling event, turn the MiniVol TAS on and begin sampling. Record the initial reading on the elapsed timer. Verify the ball height on the rotameter has settled steadily on the pre-determined seasonal reading ( from step 5.5)., adjust the ball height as necessary **Note:** The MiniVol TAS might take a few seconds to regulate the flow to the target value

**5.9** If possible, check each MiniVol TAS at approximately one-hour intervals to assure proper operation.

**5.10** After the sampling event is completed, record the final rotameter ball height, turn off the TAS then record the "End Time" on the elapsed timer on the Cr (VI) Field Sampling Event Data Sheet

**5.11** Remove the exposed filter cassette from the MiniVol TAS inlet/filter holder and place it in a clean plastic cassette mailer. After all samples have been collected they will be transported to a "clean area" for transfer to the sample shipping container for overnight shipping and delivery to the analytical laboratory. **Note :** All Cr (VI) field samples with the chain-of-custody form will be shipped overnight to arrive at the analytical laboratory within 24 hours of sampling. All samples will be logged, with the accompanying information.

**5.12** Once chain-of-custody documentation is completed and all entries verified, the samples will be prepared for overnight shipment. Sample cassette /plastic mailer assemblies should be placed in a clean Ziploc® bag and the bag should be packed with small bubble wrap snugly in a clean shipping container or cooler to prevent movement of the samples during shipment.

**5.13** To preserve the samples during transit, Blue ices will be placed inside the shipping cooler as standard practice.

**5.14** After packing, the container or cooler lid will be sealed along its entire length with wide tape.

**5.15** **Field Blank** -One field blank per sampling day will also be submitted from the same lot number as the sample filters. Field blanks will be subjected to the exact handling as the samples, except that no air is drawn through the filter cassette assembly. The handling includes loading, sealing and transporting in the field and shipping to the laboratory.

# 6.0 Sample Analysis

6.1 All filter samples including blanks and quality control samples must be analyzed within 8 days of collection. Samples must be prepared using an alkaline digestion as described in OSHA Method ID-215. The digestate is then analyzed using OSHA Method ID-215. Results are reported as total ug Cr(VI)/filter.

6.2 Final results may be reported as $\mu g/m^3$ using the following equation:

$$Cr(VI), \mu g/m^3 = Cr\ (VI)\ on\ filter\ \mu g/m^3\ air\ sampled$$

# 7.0 Quality assurance / quality control

**7.1** Field Blanks: The purpose of field blanks is to facilitate the detection of contamination that may have occurred between the initial filter manufacturing process and field handling. To accomplish this a field blank is collected by dedicating a filter cassette through the entire process of filter loading, cassette sealing, labeling, transporting to the field site, set-up, and labeling/packaging/transporting to the lab, without passing any sample air through it. In general, at least one field blank from the same lot number as the samples should be collected and analyzed per day of sampling. Details of the blank collection procedure should be described in the sample collection records.

**7.2** Chromic Acid cleaning solutions must not be used in any field or laboratory operations.

# 8.0 Data and records management

**8.1** All data, notes, comments will be documented on the Cr(VI) Sampling Event Data Sheet and in the Site Log Book as described in this procedure. All laboratory data must be recorded in a bound notebook. All documentation must be reproducible. Use black ink whenever possible, and write legibly. All records shall be placed in the project/task file immediately following sample collection.

**8.2** Unanticipated changes to the procedures or materials described in this SOP (deviations) will be appropriately documented in the project records.

**8.3** Records associated with the activities described in this SOP will be maintained according to the document management policy for the project.

# 9.0 Personnel qualifications and training

**9.1** Qualifications and training

**9.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this SOP.

**9.1.2** The individual must have prior knowledge and training of operating the Air Metric Calibration kit flow standard and the Air Metrics MiniVol TAS.

**9.2** Responsibilities

**9.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this SOP.

**9.2.2** The individual performing the work is responsible for implementing the procedures as described in this SOP and any project-specific work plans.

**9.2.3** The on-site field technician or operator is responsible for the operation and documentation of the sample collection apparatus, as well as preparation of samples for shipment to the laboratory.

Project Operating Procedure

# Operation and Calibration of a Portable Hydrogen Sulfide Monitor

## 1.0 Project Scope and applicability

### 1.1 Purpose and Applicability

This document describes the procedures that will be followed by field staff for operation and calibration of a portable hydrogen sulfide ($H_2S$) monitor. The monitor is primarily used by AECOM personnel for safety and survey monitoring of ambient air, determining the presence of hydrogen sulfide in sampling environments.

The instrumentation routinely used by AECOM personnel is the Jerome 631-X Hydrogen Sulfide Analyzer manufactured by Arizona Instrument Company. Personnel responsible for using this monitor should first read and thoroughly familiarize themselves with the instrument instruction manual.

### 1.2 Principle of Operation

The Jerome 631-X Hydrogen Sulfide Analyzer is designed for rapid detection of hydrogen sulfide vapor in ambient air. A thin gold film undergoes an increase in electrical resistance in the presence of hydrogen sulfide proportional to the mass of hydrogen sulfide present in the sample. When the SAMPLE button is pressed, an internal pump pulls ambient air over the gold film sensor for a measured period; the gold film absorbs the hydrogen sulfide and the increase in electrical resistance is converted to and displayed as parts per million (ppm) $H_2S$. During normal sampling the ambient air sample is diluted in the flow system at a ratio of 100:1. If low levels of hydrogen sulfide are expected, undiluted air samples can be drawn across the gold film sensor.

The instrument's microprocessor automatically re-zeroes the digital meter at the start of each sample cycle and freezes the meter reading until the next sample cycle is activated, thus eliminating drift between samples. During the sample mode cycle, the LCD display indicates the percentage of sensor saturation. Depending on concentration a series of 50 to 500 samples may be taken before the sensor reaches saturation. When the display indicates the sensor is near saturation a 10-minute heat cycle is required to remove the accumulated hydrogen sulfide from the sensor.

### 1.3 Specifications

Refer to the specific manufacturer's instructions for the technical specifications. This analyzer has a range of 0.003 ppm to 50 ppm $H_2S$. Response time is 12 – 52 seconds.

## 2.0 Health and safety considerations

The health and safety considerations for the site, including both potential physical and chemical hazards, will be addressed in the site-specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

This instrument is designed for vapor use only. The probe or instrument intake should not be exposed to any liquid, dust, or other foreign material.

## 3.0 Interferences

The instrument should be at the same temperature as its environment before sampling. A Zero Air Filter removes mercury vapor, mercaptans, and hydrogen sulfide from the air sample; when this filter is installed the readings should be at or near zero. Since air cooler than the instrument can cause low readings and warmer air can result in higher readings the Zero Air Filter should be used to equilibrate the instrument to ambient air temperature. Continuous sampling with clean air will not cause saturation of the gold filter but will allow the instrument to equilibrate more rapidly.

The Zero Air Filter can also be used to identify contamination within the instrument. If the readings do not reduce to near zero with the filter installed, contamination should be suspected.

The gold film sensors do not respond to the following compounds:

- Hydrocarbons
- CO, $CO_2$, and $SO_2$
- Water vapor (water vapor condensation on the gold film can cause irreparable harm to the sensor and must be avoided)

The following compounds *may* cause the gold film to respond:

- Chlorine
- Ammonia
- $NO_2$
- Most mercaptans (organic sulfur compounds or thiols)

## 4.0 Equipment and materials

- Jerome 631-X Hydrogen Sulfide Analyzer
- Probe
- Tubing Adapter
- Trimmer Tool
- Zero Air Filter
- Line Cord
- Functional Test Module
- Manufacturer’s instructions

- Field data sheets or logbook/pen

## 5.0 Procedures

### **5.1** Preliminary Steps

Preliminary steps (battery charging, check-out, calibration, maintenance) should be conducted in a controlled or non-hazardous environment.

### **5.2** Calibration

To ensure the input to the instrument contains no hydrogen sulfide or mercaptans, use a Zero Air Filter. This filter cleans the air sample and should produce sample readings of less than 0.003 ppm. With the Zero Air Filter in place, sample the air continuously until the readings stabilize.

Perform a sensor regeneration and re-zero the instrument prior to each day's use or after 30 days of storage or inactivity. Press the ON switch and the REGEN button. The instrument will begin a 10 minute regeneration cycle indicated by .H.H.H flashing on the display. **Do not interrupt this cycle**. When regeneration is complete wait 30 minutes to allow the instrument to cool then zero the sensor by pressing the ZERO button and turning the zero adjust screw under the instrument handle until the display reads 0.

The gold film sensor is inherently stable and does not require frequent calibration. It has been factory calibrated against NIST traceable permeation tubes. Calibration must be performed at the factory or an authorized calibration/repair facility. While the actual frequency depends upon the application and use, the recommended interval between calibrations is every 12 months. The Functional Test Module (FTM) provides a field check of the functionality of the instrument but does not calibrate the instrument. The FTM uses a permeation tube containing hydrogen sulfide; the flow rate and temperature of the release of hydrogen sulfide is factory calibrated to provide a specified concentration to the instrument. If the concentration falls within the expected range for the FTM being used the instrument is functioning properly; if the level is not within the expected range then the instrument must be returned for service. This calibration check is used as part of a routine maintenance routine.

### **5.3** Operation

Turn on the unit and allow it to warm up (minimum of 1 minute). The digital display should read 000. Recharge or replace the battery pack if the LO BAT indicator remains on.

Use the Zero Air Filter to equilibrate the instrument to ambient air temperature; sample continuously until the readings stabilize.

Perform sensor regeneration, wait a minimum of 30 minutes and then zero the instrument.

Press the SAMPLE button to begin sampling; during the sampling cycle the digital display will show bars to indicate the degree of sensor saturation. At the end of the sampling cycle the hydrogen sulfide

concentration is displayed in ppm; record the value. This value will remain in the display until the next sample is taken; the digital meter automatically zeroes at the start of each sample.

When sampling is completed for the day, perform sensor regeneration. Under no circumstances should hydrogen sulfide be allowed to remain on the sensor overnight.

At the end of each day, recheck the calibration. The check will follow the same procedures as the initial calibration (Section 5.2) except that no adjustment will be made to the instrument. Record the information in the field records.

When transporting, ensure that the instrument is packed in its stored condition in order to prevent damage.

### **5.4** Routine Maintenance

Perform sensor regeneration daily. Do not allow hydrogen sulfide to remain on the gold film sensor overnight. This analyzer has a range of 0.003 ppm to 50 ppm $H_2S$. Periodically check Tygon® tubing within the instrument; kinks and crimps can restrict airflow during regeneration cycle and permanently damage the sensor.

All routine maintenance should be performed in a non-hazardous environment.

### **5.5** Troubleshooting Tips

A display of .8.8.8 indicates the sensor is saturated and must be regenerated.

Changes in temperature may cause the display to show .L.L.L when taking the initial sample. Refer to the operating manual for directions on zero adjustment.

The display shows H at conclusion of sensor regeneration when zero is pressed. Check tubing for crimps and repeat regeneration cycle. If the problem is not resolved the fritware filter, intake filter disk, scrubber filters and Tygon® tubing.

High or erratic results may indicate that the internal filters are clogged. This can happen when sampling in dusty or humid areas.

A low response or erratic readings, particularly after an extended period of non-use may indicate the need for a second regeneration cycle. Wait 30 minutes before performing the second regeneration cycle.

## 6.0 Quality assurance / quality control

The end use of the data will determine the quality assurance requirements that are necessary to produce data of acceptable quality. These quality assurance requirements will be defined in the site-specific workplan or Sampling and Analysis Plan (SAP), hereafter referred to as the project plan.

Calibration of the $H_2S$ monitor will be conducted at the frequency specified in the project plan. In the absence of project-specific guidance, calibration will be performed at the beginning of each day of sampling and will be checked at the end of the sampling day or whenever instrument operation is suspect. The FTM will be used as part of a routine maintenance program to verify instrument functionality. Readings which are outside the stated acceptance range for the FTM used will require that the monitor be returned to the factory for calibration.

Checks of the instrument response (Section 5.2) should be conducted periodically and documented in the field records.

## 7.0 Data and records management

Safety and survey monitoring with the hydrogen sulfide monitor will be documented in a bound field logbook, or on standardized forms, and retained in the project files. The following information is to be recorded:

- Project name and number.
- Instrument manufacturer, model, and identification number.
- Operator's signature.
- Date and time of operation.
- Calibration check at beginning and end of day (meter readings before adjustment).
- Span setting after calibration adjustment.
- Meter readings (monitoring data obtained).
- Instances of erratic or questionable meter readings and corrective actions taken.
- Instrument checks and response verifications.

## 8.0 Personnel qualifications and training

The project manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources, and guidance necessary to perform the measurements in accordance with this POP and the project plan.

The field operator is responsible for verifying that the hydrogen sulfide monitor is in proper operating condition prior to use and for implementing the calibration and measurement procedures in accordance with this POP and the project plan.

# Field and Laboratory Measurement of pH

**Manager's Signature:**

| | |
|---|---|
| **SOP #:** | 7121 |
| **Effective Date:** | 12/29/2009 |
| **Revision #:** | 2 |
| **Method Reference:** | 2550 B |

## 1.0 SCOPE AND APPLICATION

1.1 Purpose and Applicability

This Standard Operating Procedure (SOP) provides basic instructions for routine calibration and operation of the Oakton pH/CON 300 meter. This SOP is designed specifically for the measurement of pH in accordance with Standard Method 4500-H B which address electrometric pH measurements of drinking, surface, and saline waters, domestic and industrial wastes, and acid rain.

1.2 Quality Assurance Planning Considerations

The end use of the data will determine the quality assurance requirements that are necessary to produce data of acceptable quality. These quality assurance requirements will be defined in the laboratory Quality Assurance Quality Control (QA/QC) Manual and may include duplicate or replicate measurements or confirmatory analyses.

## 2.0 RESPONSIBILITIES

2.1 The analyst is responsible for verifying that the pH meter is in proper operating condition prior to use and for implementing the calibration and measurement procedures in accordance with this SOP and the project plan.

2.2 The project manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources, and guidance necessary to perform the measurements in accordance with this SOP and the project plan.

## 3.0 REQUIRED MATERIALS

The following materials are necessary for this procedure:

- Oakton Portable Waterproof pH/Conductivity/temperature meter 9with Auto temperature correction) (model 300)
- Oakton pH/CON 300 instruction manual

- Deionized water
- Clean glass or plastic beakers or cups
- 4.0, 7.0, and 10.0 buffer solutions
- Magnetic stirrer and Teflon-coated stirring bar
- Lint-free tissues
- Mild detergent and/or 10% hydrochloric acid (for use if samples contain oily material or particulate matter)
- Calibration sheets
- Laboratory/field data sheets or logbook.

## 4.0 SUMMARY OF METHOD

The pH of a sample is determined electrometrically using either a glass electrode and a reference potential or a combination electrode.

## 5.0 SAMPLE HANDLING, PRESERVATION, AND GENERAL MEASUREMENT PROCEDURES

5.1.1 To achieve accurate pH measurements, samples shall be analyzed within 15 minutes of collection. Sample should be collected in plastic or glass containers.

5.1.2 After measuring a sample containing oily material or particulate matter, the electrode must be cleaned by carefully wiping with a lint-free cloth, or washing gently in a mild detergent, followed by a deionized water rinse. If this does not suffice, an additional rinse with 10% hydrochloric acid (followed by de-ionized water) may be needed.

5.1.3 As temperature can affect the pH measurements obtained, both the pH and the temperature of the sample must be recorded.

5.1.4 Calibration must include a three point calibration that bracket the expected pH of the samples to be measured.

5.1.5 Primary standard buffer salts available from NIST can be purchased and are necessary for situations where extreme accuracy is required. Secondary standard buffers may be purchased as a solution from commercial vendors and are recommended for routine use. Buffers should not be used after their expiration dates as provided by the manufacturer. If the manufacturer does not supply an expiration date or if the buffers are prepared from pH powder pillows, etc., an expiration date of one year from purchase or preparation should be used. All standards must be labeled with manufacturer, lot number, receipt date, opened date, and expiration date.

5.1.6 When the meter is being used in the field, move the probe in a way that creates sufficient sample movement across the sensor; this insures homogeneity of the sample and suspension of solids. If sufficient

movement has occurred, the readings will not drift (<0.1 pH units). Rinse the electrode with deionized water between samples and wipe gently with a lint-free tissue.

5.1.7 Fluctuating readings may indicate more frequent instrument calibrations are necessary.

5.2 Calibration and Measurement Procedures

5.2.1 The pH meter must be calibrated daily before any analyses are performed. The instrument serial # should be noted in the log book. The meter should be checked every 3 hours against one of the buffers, and the value recorded. If the measurement is off by more than 0.2, the instrument needs to be re-calibrated.

5.2.2 A duplicate pH reading must be made for every twenty (20) samples measured in the field for any given parameter. The duplicate results must be reported with its corresponding sample results. Duplicate results must be within 0.10 standard units of the original analysis result.

5.2.3 Connect the electrode to the meter. Choose either 7.0 and 10.0 (high range) or 4.0 and 7.0 (low range) buffers, whichever will bracket the expected sample range. Place the buffer in a clean beaker. If the pH is being measured in a laboratory, place the beaker on the magnetic stirrer and place the stirring bar in the beaker. Measure and record the temperatures of the buffers using a calibrated thermometer or automatic temperature compensation (ATC).

5.2.4 Place the electrode into the 10.0 buffer or into the 7.0 buffer. (The calibration procedure described here begins with the buffer of the highest pH selected. The instrument manufacturer's calibration instructions may suggest starting with the buffer of the lowest pH selected).

5.2.5 Adjust the instrument calibration according to the Oakton instruction manual. Discard the buffer and rinse the beaker and stirring bar thoroughly with de-ionized water.

5.2.6 Refill the beaker with the 7.0 buffer or the 4.0 buffer. Rinse the electrode, gently wipe it with a lint-free tissue, and place it in the selected buffer solution. If the pH is being measured in a laboratory, place the beaker on the magnetic stirrer and place the stirring bar in the beaker. Continue adjusting the instrument calibration according to the manufacturer's instructions. Record the electrode slope (if provided by the instrument) on the calibration sheet (an acceptable slope is between 92 and 102 percent). Measure and record the temperature of the buffer using a calibrated thermometer or ATC. Discard the buffer and rinse the beaker and stirring bar thoroughly with deionized water.

5.2.7 After calibration, the instrument shall be checked against the calibration buffers. Calibration is valid if buffers read within 0.10 standard units of their certified values.

5.2.8 An additional check may be performed, if required by the project plan, by placing the electrode into an additional buffer solution. This buffer should be from a different source than the buffers used for the initial calibration. This buffer should read within +0.2 pH units of the buffer's true pH value if after three hours of use.

5.2.9 Verify the calibration every 20 samples and after the last sample of the day with a buffer solution prepared from a different source than that used for initial calibration. Recalibrate the instrument if the check value varies more than 0.2 pH units from the true value.

5.2.10 The electrode will be rinsed with deionized water and wiped gently with a lint-free tissue between sample analysis.

5.2.11 Recalibrate the instrument if the buffers do not bracket the pH of the samples.

5.2.12 The meter must be re-calibrated following any maintenance activities and prior to the next use.

5.3 Troubleshooting Information

If there are any performance problems with the pH meter which result in inability to achieve the acceptance criteria presented in Section 5.0, consult the appropriate section of the meter instruction manual for the checkout and self-test procedures. If the problem persists, consult the manufacturer's customer service department immediately for further instructions.

5.4 Maintenance

5.4.1 Instrument maintenance should be performed according to the procedures and frequencies required by the manufacturer.

5.4.2 The electrode must be stored and maintained according to the manufacturer's instructions.

5.4.3 If an instrument with ATC is being used, the device should be checked on a quarterly basis for accuracy with an NIST thermometer.

## 6.0 QUALITY CONTROL

6.1 Duplicate measurements of a single sample will be performed of at least 1 per every 20 samples. Duplicate measurements should agree within +0.1 pH units.

6.2 The temperature readout of the meter will be checked quarterly against an NIST-traceable thermometer. If the difference is greater than 0.2□C, the instrument manufacturer will be consulted for instructions. Temperature measurements will be compensated for any difference with the reference thermometer.

## 7.0 REPORTING

7.1 All pH meter calibration, temperature check, and maintenance information will be recorded on a daily calibration sheet. pH data may be recorded on the appropriate laboratory or field data sheets or logbooks.

7.2 Calibration documentation must be maintained in a thorough and consistent manner. At a minimum, the following information must be recorded:

- Date and time of calibration

- Signature or initials of person performing the measurement
- Instrument identification number/model
- Expiration dates and batch numbers for all buffer solutions
- Reading for pH 7.0 buffer before and after meter adjustment
- Reading for pH 4.0 or 10.0 buffer before and after meter adjustment
- Readings for all continuing calibration checks
- Temperature of buffers (corrected for any difference with reference thermometer), including units
- Slope reading (if provided by instrument)
- Comments

7.3 Documentation for recorded data must include a minimum of the following:

- Date and time of analysis
- Signature or initials of person performing the measurement
- Instrument identification number/model
- Sample identification/station location
- Temperature (corrected for any difference with reference thermometer) and pH of sample (including units and duplicate measurements)
- Comments
- All calibration records (logs) must be retained for five years.

## 8.0 TRAINING/QUALIFICATIONS

To properly perform pH measurements, the analyst must be familiar with the calibration and measurement techniques stated in this SOP. The analyst must also be experienced in the operation of the meter.

Certain state certification programs require that pH measurements in the field be taken by, or in the presence of, personnel that are qualified under the certification program.

Project Operating Procedure

# Decontamination of Field Equipment

## 1.0 Purpose and applicability

This Standard Operating Procedure (SOP) provides basic instructions for routine measurement of Dissolved Oxygen (DO) using Oakton Portable Waterproof Dissolved Oxygen Meter (Model 35641). It is noted that this instrument is a combination DO/temperature meter.

This SOP, which has been prepared pursuant to the requirement of NJAC7:18-8, addresses DO measurement only.

This SOP applies when performing “analyze immediately” DO measurements on regulatory samples, in accordance with Standard Method SM 4500 O G, for DO measurement in drinking, surface and saline waters, and domestic and industrial wastewaters.

## 2.0 Summary of method

Dissolved oxygen levels in natural and waste waters depend on the physical, chemical, and biochemical activities in the water body.

This meter uses a galvanic probe. It consists of a cell that contains electrolyte and that is enclosed by a selective membranes, and two metallic electrodes. The membrane is practically impermeable to water and ionic dissolved matter, but is permeable to oxygen and a few other gasses.

The cathode consumes the oxygen passed through the membrane, and produces an electric current in the probe; this current is proportional to the partial pressure of oxygen in the sample.

## 3.0 Responsibilities

The analyst is responsible for verifying that the DO meter is in proper operating condition prior to use, and for operating the meter in accordance with manufacturers’ instructions. The analyst is also responsible for implementing and documenting the calibration and measurement procedures in accordance with the manufacturers’ instructions, this SOP and the project plan.

The project manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources and guidance necessary to perform the measurements in accordance with this SOP and the project plan.

## 4.0 Required materials

The following materials are necessary for this procedure:

- Oakton Portable Waterproof DO meter (Model 35641)
- Oakton instruction manual
- Deionized Water

- Field logbook
- Lint free cloth

## 5.0 Sample handling and general measurement procedures

To achieve accurate temperature measurements, samples must be analyzed within 15 minutes of collection. Samples should be collected in glass or plastic containers.

Since the cathode consumes the oxygen in the sample, it is essential that the fluid flow past the sensor to maintain accurate readings. Therefore, when the meter is being used in the field, if necessary, move the probe in a way that creates sufficient sample movement across the sensor. This insures homogeneity of the sample. If sufficient movement has occurred, the readings will not drift. Rinse the electrode with deionized water between samples and wipe gently with a lint free cloth.

The solubility of oxygen in water varies with barometric peruse and temperatures, and decreases as salinity increases. For the most accurate DO readings, you need to compensate for these factors. This meter automatically compensates for temperature readings. It also allows you to enter a salinity correction factor and the barometric pressure to correct this variability. A pressure vs. altitude table is included in the equipment instruction booklet. Consult manufacturer's instructions if it becomes necessary to adjust the instrument from factory default settings for salinity and/or barometric pressure.

After measuring a sample containing oily material or particulate matter, the electrode may need to be cleaned using a deionized water rinse and/or by carefully wiping with a damp lint-free cloth.

## 6.0 Calibration and measurement procedures

The DO meter must be calibrated daily before any analyses are performed. The meter shall be calibrated in accordance with the manufacturer's instructions. The instrument serial number should be noted in the field book.

A duplicate DO reading must be made for every twenty samples measured in the field. The duplicate result must be reported with its corresponding sample result. Duplicate results must be within 10% of the original analysis result and recorded in the field book.

The electrode will be rinsed with deionized water and wiped gently with a lint-free tissue between sample analyses.

The meter must be re-calibrated following any maintenance activities and prior to the next daily use.

The built-in temperature sensor included in the probe is factory calibrated. Calibrate your sensor only if you suspect drift that may have occurred over a long period of time or if you have a replacement probe. Calibration is performed using a NIST traceable thermometer, in accidence with manufacturer's instruction.

The instrument will be calibrated for DO measurement precision weekly when in use using the Winkler Method.

## 7.0 Troubleshooting information

If there are any performance problems with the DO meter which result in inability to achieve the acceptance criteria presented in Section 6 (+/- 10%), consult the appropriate section of the meter instruction manual for the troubleshooting procedures. If the problem persists, consult the manufacturer's customer service department immediately for further instructions.

## 8.0 Probe care

The probe is a galvanic measuring element which produces an output proportional to the oxygen present in the medium in which it is placed. The galvanis probe design lets you take measurements immediately- without the typical 15 minute wit of other dissolved probes.

The probe consists two parts:

- An upper part consisting of an anode, a cathode, and cable; and
- A lower part consisting of a membrane cap, membrane, and electrolyte.

Under typical operating control conditions, the probe should last for several years. Proper care and maintenance will help you receiver the maximum probe life and ensure more accurate readings. Since any deposits on the membrane surface act as a barrier to oxygen diffusing through the membrane, the membrane must be cleaned at regular intervals to assure maximum reliability. After using the probe, rinse the probe in clean water and wipe it with a soft cloth or paper to avoid any hardening of deposits. If growth develops on the probe, use a disinfecting chemical to clean.

NOTE: Although the membrane is strong and not easily damaged, wipe it gently while cleaning it. If the membrane is damaged or torn, the probe will no longer function. There are no special probe storage requirements.

## 9.0 Quality control

A duplicate measurement of a single sample will be performed of at least 1 per every20 samples. Duplicate DO measurements should agree within +/- 10%. Duplicate temperature measurements should agree within 1.0 degree Fahrenheit.

The instrument will be calibrated quarterly when in use using the Winkler method. The temperature probe will be calibrated against an NIST traceable thermometer. Calibration records will be maintained by AECOM's Laboratory Manager. Records will be kept on the file for at least 5 years.

## 10.0 Reporting

All daily DO meter calibration and maintenance information, as well as DO data, will be recorded on the appropriate laboratory or field data sheets or field logbook.

At a minimum, the following information must be recorded:

Date and time of calibration

Instrument identification number/model

Signature or initials of person performing the measurement

Documentation for recorded data must include a minimum of the following:

Data and time of analysis

Signature or initials of person performing the measurement

Instrument identification number/model

Sample identification/ station location

Temperature and DO readings

Comments

## 11.0 Training/qualifications

To properly perform temperature measurements, the analyst must be familiar with the calibration and measurement techniques stated in this SOP. The analyst must also be experienced in the operation of the meter.

Certain state certification programs require that temperature measurements in the field be taken by, or in the presence of, personnel that are qualified under the certification program.

|---|---|
| | **SOP #:** 7123 |
| | **Effective Date:** 12/29/2009 |
| | **Revision #:** 2 |
| | **Method Reference:** 2550 B |

## 1.0 SCOPE AND APPLICATION

**1.1** Purpose and Applicability

This Standard Operating Procedure (SOP) provides basic instructions for routine measurement of temperature using the Oakton pH/CON 300 meter. It is noted that this instrument is a combination pH/temperature meter. This SOP addresses temperature measurement only (other capabilities are outlined in the appropriate SOP). This SOP is designed specifically for the measurement of temperature in accordance with Standard Method 2550 B which address thermometric temperature measurement of drinking, surface, and saline waters, and domestic and industrial wastes.

**1.2** Quality Assurance Planning Considerations

The end use of the data will determine the quality assurance requirements that are necessary to produce data of acceptable quality. These quality assurance requirements will be defined in the laboratory Quality Assurance Quality Control (QA/QC) Manual and may include duplicate or replicate measurements or confirmatory analyses.

## 2.0 RESPONSIBILITIES

**2.1** The analyst is responsible for verifying that the Oakton pH/CON 300 meter is in proper operating condition prior to use and for implementing the calibration and measurement procedures in accordance with this SOP and the project plan.

**2.2** The project manager is responsible for ensuring that project-specific requirements are communicated to the project team and for providing the materials, resources, and guidance necessary to perform the measurements in accordance with this SOP and the project plan.

## 3.0 REQUIRED MATERIALS

The following materials are necessary for this procedure:

- Oakton Portable Waterproof ph/Conductivity/Temperature meter (model 300)
- Oakton pH/CON 300 meter instruction manual
- National Institute of Standards and Technology (NIST)-traceable thermometer
- Laboratory or field data sheets or logbooks
- Clear glass or plastic containers

## 4.0 SUMMARY OF METHOD

The temperature of a sample is determined electrometrically using a temperature sensor. The Oakton pH/CON 300 meter displays temperature in the range of -10.0 to 110 $^{o}$C simultaneously with sample results. The meter can display measurement values to tenths (0.0), hundredths (0.00) or thousandths (0.000). The default is hundredths. The meter can display temperature in $^{o}$C or $^{o}$F.

## 5.0 SAMPLE HANDLING, PRESERVATION, AND GENERAL MEASUREMENT PROCEDURES

To achieve accurate temperature measurements, samples shall be analyzed within 15 minutes of collection. Samples should be collected in glass or plastic containers.

**5.1** Calibration and Measurement Procedures

**5.1.1** The Oakton pH/CON 300 meter will, at a minimum, be checked quarterly as described in Section 5.0. The device will be checked against an NIST-traceable thermometer and the necessary compensation made for the difference in temperature 0.5 $^{o}$C or greater

**5.1.2** Immerse the Oakton pH/CON 300 meter into the sample.

**5.1.3** Swirl and take a reading when the value stabilizes.

**5.1.4** Record the temperature reading to the nearest 0.1$^{o}$.

**5.1.5** The Oakton pH/CON 300 meter will be deployed in accordance with the manufacturer's instruction manual. For water-column profiling operations (if applicable) the sensor readings will be recorded manually in a designated field logbook or continuously through the use of a computer. An internal data-logger will be used for recording sensor measurements during moored deployment of a sensor. The frequency of data recording will be specified in the project plan. The location, date, and time of sensor deployment, along with depth (of measurement or mooring) will be recorded in

conjunction with the temperature sensor data. Additional documentation requirements are listed in Section 6.2.

**5.1.6** Temperature data may be post-calibrated using any of a variety of calibration data including, but not limited to, field calibration points, manufacturer calibration data, and analytical results from samples collected during field deployment of the sensors. The decision criteria for post calibration, and the technique used, will be specified in the project plan, and will be consistent with the manufacturer's recommendations.

**5.2** Troubleshooting Information

If there are any performance problems with the Oakton pH/CON 300 meter, consult the appropriate section of the meter instruction manual for the checkout and self-test procedures. If the problem persists, consult the Oakton customer service department immediately for further instructions. If performance problems exist with the probe, repair or replace the temperature sensor.

**5.3** Maintenance

Instrument maintenance for meter-type temperature measuring devices should be performed according to the procedures and frequencies specified by Oakton.

## 6.0 QUALITY CONTROL

**6.1** The Oakton pH/CON 300 meter will, at a minimum, be checked against an NIST-traceable thermometer at the frequency stated in section 5.1.1 (quarterly). This verification procedure will be performed as follows:

- Immerse the temperature sensor and the NIST-traceable thermometer into a sample.
- Allow the readings to stabilize.
- Record the readings and document the difference.
- Label the temperature sensor with the correction value/adjustment and the date the accuracy check was performed. A correction factor is required only when the difference between the NIST thermometer and the probe equals or exceeds 0.5 $^{o}$C.
- Compensate for the difference when sample measurements are taken.
- Record the thermometer IDs, the temperature from the NIST-traceable thermometer, the temperature from the thermometer being verified, the time, date and the initials of the analyst, and any required correction factor.

**6.2** A duplicate measurement must be made for every twenty (20) samples measured in the field for temperature measurements. It is noted that duplicate measurements should agree within $\pm$0.5$^{o}$C or approximately $\pm$1.0$^{o}$F.

## 7.0 REPORTING

**7.1** Records for checking the accuracy of the Oakton pH/CON 300 meter (where applicable) will include:

- Date
- Temperature probe checked
- Reference thermometer number
- Readings for reference thermometer and temperature probe being checked
- Adjustment made for difference in readings
- Initials of analyst

**7.2** Documentation for recorded data must include a minimum of the following:

- Date and time of analysis
- Signature or initials of person performing the measurement
- Thermometer ID number or instrument identification number/model
- Sample identification/station location
- Temperature of sample (including units and duplicate measurements) compensated for any difference with the reference thermometer if applicable
- Comments
- Records will be kept on file for at least 5-years.

## 8.0 TRAINING/QUALIFICATIONS

To properly perform temperature measurements, the analyst must be familiar with the calibration and measurement techniques stated in this SOP. The analyst must also be experienced in the operation of the meter.

Certain state certification programs require that temperature measurements in the field be taken by, or in the presence of, personnel that are qualified under the certification program.

## 1.0 Scope and Application

This procedure is applicable to the field measurement of turbidity in groundwater, drinking water, or surface water using the LaMotte 2020 turbidimeter. Turbidity is an expression of the optical property that causes light to be scattered or absorbed rather than transmitted in straight lines through a sample (the higher the intensity of scattered light, the higher the turbidity). Turbidity in water is caused by the presence of suspended matter such as clay, silt, finely divided organic and inorganic material, and microscopic organisms. Turbidity should not be confused with color, since a darkly colored water can still be clear and not turbid.

## 2.0 Summary of Method

The LaMotte 2020 turbidimeter is a portable, microprocessor controlled Nephelometer. The LaMotte 2020 turbidimeter measures scattered light in the sample at 90 degrees from the light source. A reference beam passes through the sample and is measured at 180 degrees from the light source. The ratio of these two readings is electronically converted to a turbidity measurement in nephelometric turbidity units (NTU). The light source for the LaMotte 2020 turbidimeter is a tungsten incandescent light bulb operated at 2,800 degrees Kelvin, and the light is detected by two silicon photo diodes (one at 90 degrees from the light source and one at 180 degrees from the light source). The multi-detector optical configuration assures long term stability and minimizes stray light and color interferences. All readings are determined by the process of signal averaging over a five second period, minimizing fluctuations in readings attributed to large particles and enabling rapid, repeatable measurements. A picture of the LaMotte 2020 turbidimeter is presented as Figure 2-1. A diagram illustrating how the LaMotte 2020 turbidimeter measures turbidity is presented as Figure 2-2.

The LaMotte 2020 turbidimeter is pre-calibrated by the manufacturer to a range of 0 to 1,100 NTU with AMCO™ primary standards. Recalibration of the LaMotte 2020 is not required by the user. However, a procedure to standardize the calibration is performed to obtain the most accurate readings over a narrow range using two AMCO™ standards of 1.00 NTU and 10.0 NTU, which are supplied with the LaMotte 2020.

For operation of the LaMotte 2020 turbidimeter, a sample is collected into the LaMotte 2020 turbidity vial. The vial is placed into the LaMotte 2020 sample chamber, the sample chamber is closed, and the READ button is pressed. A walking dash "—" is displayed while the LaMotte 2020 turbidimeter analyzes the sample. After five seconds, the turbidity in NTU is displayed.

## 3.0 Health and Safety Warnings

3.1 Refer to the site-specific heath and safety plan for cautions and health and safety procedures associated with the samples to be analyzed.

3.2 Caution should be taken when working with all chemicals. Refer to the Material Safety Data Sheets (MSDSs) for the chemicals to be used. The MSDSs are located in the site-specific health and safety plan.

**Figure 2-1. The LaMotte 2020 Turbidimeter**

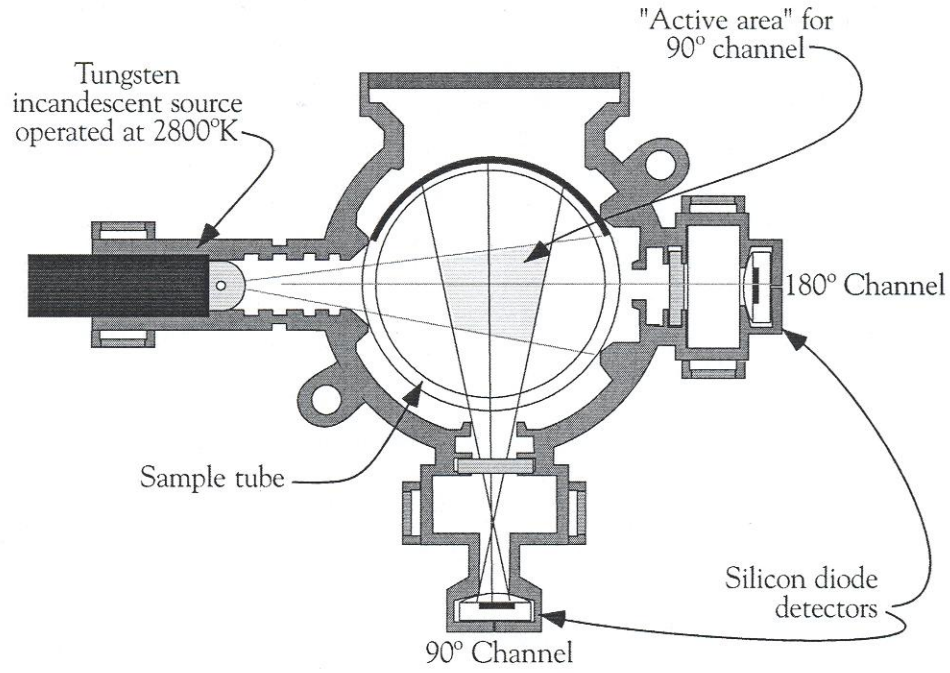

**Figure 2-2. How the LaMotte 2020 measures turbidity**

3.3 The LaMotte 2020 turbidimeter should not be stored or used in a wet or corrosive environment. Care should be taken to prevent water from wet turbidity tubes from entering the turbidimeter light chamber. NEVER PUT WET TURBIDITY TUBES IN THE TURBIDIMETER.

3.4 If operating the LaMotte 2020 turbidimeter in an environment where the temperature is less than or equal to 0° C, be sure to remove the turbidity standards from the LaMotte 2020 turbidimeter case, as the standards will freeze and crack the turbidity vials if exposed to temperatures less than or equal to 0° C.

**4.0 Interferences**

4.1 The presence of floating debris, coarse sediments, or air bubbles will cause high readings.

4.2 The presence of light absorbing materials (such as activated carbon) will cause low readings.

4.3 Excessive color in a sample will absorb light and cause high readings. If the turbidity readings appear to be biased high due to excessive color in the sample, use professional judgment when interpreting the turbidity results. This should be noted on the monitoring well worksheet or the field logbook.

4.4 Extreme care should be taken when handling the turbidity standards or the turbidity vial, as surface scratches or finger smudges will cause analytical errors. Handle these items by the top only.

4.5 Do not shake or freeze samples or turbidity standards.

4.6 Do not operate the LaMotte 2020 turbidimeter near electric motors. The electric field created by electric motors can affect turbidity readings on the LaMotte 2020 turbidimeter.

4.7 The LaMotte 2020 turbidimeter should be placed on a surface free from vibration. Vibrations can cause high turbidity readings on the LaMotte 2020 turbidimeter.

## 5.0 Personnel Qualifications

All field samplers are required to take the 40-hour OSHA Hazardous Waste Operations training course and annual 8-hour refresher training prior to engaging in any field collection activities. Prior to the implementation of this SOP, all field samplers will be instructed by a person experienced with the LaMotte 2020 turbidimeter and this SOP. All field samplers must demonstrate to the field team leader and/or Project Chemist the proper procedures for calibration and operation of the LaMotte 2020 turbidimeter prior to sample analysis.

## 6.0 Equipment and Supplies

- Copy of the Health and Safety Plan and Sampling and Analysis Plan
- LaMotte 2020 turbidimeter
- LaMotte 2020 turbidimeter turbidity tubes
- AMCO™ 1.00 NTU and 10.0 NTU turbidity standards
- Kimwipes® Absorbent Wipes
- Backup 9-volt battery
- Deionized, ultra-filtered (DIUF) water
- Turbidity free water
- ¾" circular stickers
- thermometer

## 7.0 Procedure

7.1 Setting the Operating Mode

The LaMotte 2020 turbidity meter has two operating modes: standard operating mode and EPA mode. The standard operating mode displays the measured turbidity to the full resolution of the instrument. The EPA mode displays the measured turbidity rounded to the reporting requirements of the EPA and Standard Methods compliance monitoring programs. Operating in EPA mode eliminates the need for the user to manually round off turbidity results according to EPA specifications. The EPA requires these reporting requirements because it recognizes the inherent accuracy limitations of turbidity measurements within the specified ranges.

The LaMotte 2020 turbidity meter can only be switched from one mode to the other while turning the instrument on from the off state. The LaMotte 2020 turbidity meter will remain in which ever mode it was last used, even if the meter has been turned off. To switch from one mode to the other, perform the following procedure:

7.1.1 Turn off the LaMotte 2020 turbidimeter if it is on.

7.1.2 Press the **CAL** button and hold it down while pressing the **READ** button to turn the LaMotte 2020 turbidimeter on.

7.1.3 The LaMotte 2020 turbidimeter will come on in the opposite mode than it was in previously. If the LaMotte 2020 is in EPA mode, an up arrow (▲) will be visible in the upper left hand corner of the instrument display.

7.2 Calibration of the Turbidity Tubes

If the LaMotte 2020 is supplied by a rental agency (e.g. U.S. Environmental, Pine Environmental), calibration of the turbidity tubes is usually not needed, as this procedure is performed by the rental agency and the turbidity tube with the lowest reading is usually supplied with the turbidimeter. If the LaMotte 2020 turbidimeter is purchased, or if this step was not performed by the rental agency and more than one turbidity vial is provided with the LaMotte 2020, perform the following procedure.

7.2.1 Record the ambient temperature.

7.2.2 Allow the calibration standards to equilibrate to ambient temperature.

7.2.3 Fill each turbidity tube with DIUF water.

7.2.4 Analyze and record the turbidity reading for each turbidity tube according to the procedures presented in Section 7.4.

7.2.5 Mark the tube with the lowest turbidity reading by placing a ¾" circular sticker on the top of the lid of the tube and writing an "R" on the sticker for reference tube.

7.2.6 Follow the calibration procedures presented in Section 7.3, using the reference turbidity tube and the 1.00 NTU or 10.0 NTU AMCO™ standard.

7.2.7 Fill the remaining turbidity tubes with the same AMCO™ standard as in the reference turbidity tube.

7.2.8 Analyze and record the turbidity reading for each tube according to the procedures presented in Section 7.3.

7.2.9 The difference between the true value of the AMCO™ standard (1.00 NTU or 10.0 NTU) and the value produced when the turbidity tube with the AMCO™ standard is analyzed is the correction

factor for that tube. Place a ¾' circular sticker on the top of the lid of the turbidity tube and write the correction factor on the sticker. This correction factor should be used when comparing results from different tubes.

In most cases, comparison of results from different tubes is not necessary, and only steps 7.2.1 through 7.2.3 need to be performed in order to determine which turbidity tube produces the lowest reading.

7.3 Calibration of the LaMotte 2020 Turbidimeter

7.3.1 Record the ambient temperature.

7.3.2 Allow the calibration standards to equilibrate to ambient temperature.

7.3.3 Select the AMCO™ standards (1.00 NTU or 10.0 NTU) in the range of the samples to be tested. In most cases this will be the 10.0 NTU standard.

7.3.4 Fill the reference turbidity tube (see section 7.2) with the standard, cap the reference turbidity tube, and wipe the reference turbidity tube with a Kimwipe®. **NOTE:** If the LaMotte 2020 Turbidimeter is provided by a rental agency, the rental agency will most likely supply the two AMCO™ standards in capped turbidity tubes that are dedicated to each standard. Therefore, pouring of the AMCO™ standard into the reference turbidity tube is not necessary.

7.3.5 Open the lid on the LaMotte 2020 turbidimeter. Align the indexing arrow on the turbidity tube with the indexing arrow just below the sample chamber on the LaMotte 2020 turbidimeter (see Figure 7-1), and insert the turbidity tube into the sample chamber.

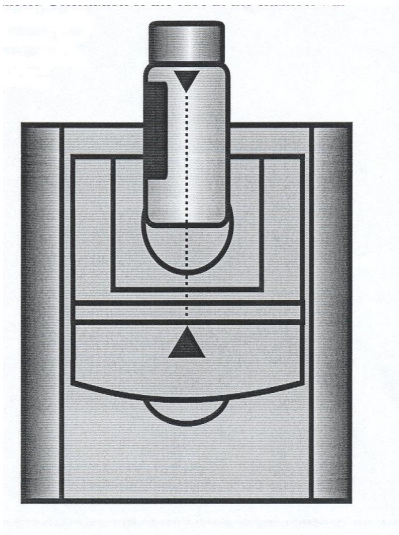

**Figure 7-1 Aligning the Index Arrows on the Turbidity Tube and the LaMotte 2020 Turbidimeter**

7.3.6 Close the lid on the LaMotte 2020 turbidimeter and press the **READ** button. The turbidity in NTU will be displayed in five seconds. If the displayed value is within +/- 5% of the true value of the AMCO™ standard, record the reading on the turbidity calibration log sheet, and indicate in the comments column of the turbidity calibration log sheet that the reading was obtained through a calibration check, and the LaMotte 2020 turbidimeter did not require calibration. If the displayed value is not within +/- 5%of the true value of the AMCO™ standard, continue with the calibration procedure.

7.3.7 Push the **CAL** button for five seconds until **CAL** is displayed on the LaMotte 2020 turbidimeter, and release the **CAL** button. The display will flash the reading obtained in step 7.3.6.

7.3.8 Adjust the display with the ▲ or ▼ buttons until the true value of the AMCO™ standard is displayed on the LaMotte 2020 turbidimeter.

7.3.9 Push the **CAL** button again to memorize the calibration. The LaMotte 2020 turbidimeter display will stop flashing, indicating that calibration is complete. Press the **READ** button again to verify that the calibration is acceptable. If the reading is not within +/- 5% of the true value of the AMCO™ standard, the LaMotte 2020 turbidimeter must be recalibrated by repeating steps 7.3.1 through 7.3.9.

7.3.10 Once an acceptable calibration check has been performed, record the reading on the turbidity calibration log sheet, and indicate in the comments column of the turbidity calibration log sheet that the reading was a calibration check obtained following calibration.

7.3.11 Repeat the calibration check using a second standard to bracket the expected values. For low-flow groundwater sampling, deionized ultra-filtered water (0.00 NTU) should be used unless elevated turbidity is expected. Repeat steps 7.3.4 and 7.3.6. The value should be within ± 0.10 NTU. If criteria are not met, check the cleanliness of the tube, check the standard for air bubbles, and repeat the check. If the error cannot be corrected, recalibrate, or use another meter.

7.4 Sample Analysis

7.4.1 Rinse an empty turbidity tube with a portion of the sample, and shake out the excess sample water.

7.4.2 Fill the reference turbidity tube to the neck. The turbidity tube should be filled in a manner such that the sample water is entering the turbidity tube down the side of the turbidity tube to avoid creating bubbles.

7.4.4 Cap the turbidity tube and wipe the turbidity tube dry with a clean Kimwipe®.

7.4.5 Gently mix the sample by inverting the turbidity tube. Be careful not to introduce any bubbles into the turbidity vial.

7.4.6 Open the lid on the LaMotte 2020 turbidimeter. Align the indexing arrow on the turbidity tube with the indexing arrow just below the sample chamber on the LaMotte 2020 turbidimeter (see Figure 7-1), and insert the turbidity tube into the sample chamber.

7.4.7 Close the lid on the LaMotte 2020 turbidimeter and press the **READ** button. The turbidity in NTU will be displayed in five seconds.

7.4.8 Use a graduated cylinder and turbidity free water to dilute any sample that is over 1,100 NTU, such that the reading falls within the LaMotte 2020 turbidimeter's calibrated range (0 to 1,100 NTU). Calculate final turbidity according to the following formula:

*Turbidity (NTU) = sample_reading x dilution_factor*

Record the results on the monitoring well worksheet or the field logbook.

7.4.9 The LaMotte 2020 turbidimeter will turn off automatically two minutes after the last button push. To turn the LaMotte 2020 turbidimeter off manually, press and hold the **READ** button for at least one second. Release the **READ** button when "0FF" is displayed.

## 8.0 Data and Records Management

All calibration/calibration check information must be documented on the turbidity calibration log sheet. An example turbidity calibration log sheet is presented in Attachment A. All sample data and relevant information (e.g. sample collection method used) must be documented on field data sheets (e.g. groundwater monitoring worksheets, surface water sampling worksheets) or within site log books with permanent ink. Data recorded will include the following:

- Instrument make, model, and serial number
- Date, time, and results of instrument calibration and calibration checks
- Deviations from the procedure as written
- Readings obtained, including any dilutions

## 9.0 Quality Control and Quality Assurance

9.1 The LaMotte 2020 turbidimeter will be calibrated at the start of each day of sample analysis according to the procedures described in Section 7.3. If a parameter is measured that lies outside of the range bracketed by the instrument calibration standards, the instrument must either be recalibrated using standards that bracket the value or a calibration check using a standard that brackets the value must be performed. If the standards are not available to bracket the result, the data must be qualified.

9.2 Readings measured by instruments that are subsequently found to be outside of criteria during the calibration check shall be documented on the sampling worksheet used to document the sample collection.

9.3 If the LaMotte 2020 turbidimeter is being used in fieldwork (e.g. groundwater sampling or surface water sampling), the calibration will be checked each day prior to calibration, immediately after calibration (if calibration is required as described in Section 7.3), and at the end of each day using the same AMCO™ standard as was used for calibration. The reading must be within +/- 5% of the true value (± 0.10 NTU for the zero standard). If this criteria is not met, the source of the problem must be identified and corrected, or another turbidimeter must be used.

9.4 If the LaMotte 2020 turbidimeter is being used in a field laboratory setting (e.g. pilot groundwater treatability study), the calibration will be checked each day prior to calibration, immediately after calibration (if calibration is required as described in Section 7.3), at the midpoint of each day, and at the end of each day using the same AMCO™ standard as was used for calibration. The reading must be within +/- 5% of the true value. If this criteria is not met, the source of the problem must be identified and corrected, or another turbidimeter must be used.

## 10.0 Troubleshooting and Maintenance

The LaMotte 2020 turbidimeter is not designed for field service with the exception of battery replacement. See the Instructions Manual presented in Attachment B for detailed descriptions of troubleshooting and maintenance procedures. Some common troubleshooting and maintenance procedures are presented below.

10.1 "BAT" is displayed – The battery is low and needs to be changed.

10.1.1 Open the battery compartment lid on the bottom of the LaMotte 2020 turbidimeter

10.1.2 Remove the 9-volt battery from the battery compartment, disconnect and remove the 9-volt battery from the polarized plug

10.1.3 Carefully connect a new 9-volt battery to the polarized plug and insert it into the battery compartment.

10.1.4 Close the battery compartment lid.

10.2 "ER1" is displayed – The battery is very low and needs to be changed immediately. **Operating the LaMotte 2020 turbidimeter with a very low battery could result in permanent erasure of the factory calibration. Change the battery according to the procedures outlined in steps 10.1.1 through 10.1.4 immediately.**

10.3 "ER2" is displayed – The sample result is above the calibration range (>1,100 NTU). Dilute the sample with turbidity free water and reanalyze.

10.4 "ER3" is displayed – The tungsten incandescent light bulb is misaligned or burnt out. Call LaMotte for procedures on returning the instrument to the manufacturer.

Attachment: Calibration Log

## 1.0 Scope and Application

The purpose of this standard operating procedure (SOP) is provide a framework for calibrating sondes used to measure water quality parameters for ground water and surface water. Water quality parameters include temperature, pH, dissolved oxygen, conductivity/specific conductance, and oxidation reduction potential. Turbidity must not be measured using the portable water quality meters since the method used by the YSI and other models for turbidity measurement may not be approved for use by EPA, and because the flow-through cell acts as a sediment trap. A separate meter which uses EPA Method 180.1 or Standard Method 3130 B to measure turbidity must be used.

This SOP is written specifically for the YSI model 6-Series Sondes (which include the 600R, 600XL, 600XLM, 6820, 6920 and 6600 models), and the YSI 650 MDS (Multi parameter Display System) display/logger. Note that the YSI 6820 is the equipment model typically used. The general calibration processes discussed herein are applicable to other manufactures sondes and displays/loggers. Consult the manufacturer's instruction manuals for specific procedures.

## 2.0 Summary of Method

This SOP describes the process for calibration using YSI Model 6-Series Sondes for water quality field measurements.

## 3.0 Health and Safety Warnings

3.1 All proper personal protection clothing and equipment is to be worn.

3.2 The standard solutions for calibrating conductivity contain iodine, potassium chloride and propanol. When using the standards, avoid inhalation, skin contact, eye contact or ingestion. If skin contact occurs, remove contaminated clothing immediately. Wash the affected areas thoroughly with large amounts of water. If inhalation, eye contact or ingestion occurs, consult the Material Data Safety Sheets (MSDS) for prompt action, and in all cases seek medical attention immediately.

3.3 All standard solutions for calibration pH contain the following chemicals:

- pH 4 Solutions: potassium hydrogen phthalate, formaldehyde, water
- pH 7 Solutions: sodium phosphate (dibasic), potassium phosphate (monobasic), water
- pH 10 Solutions: potassium borate (tetra), potassium carbonate, potassium hydroxide, sodium diethylenediamine tetraacetate, water

Avoid inhalation, skin contact, eye contact and ingestion. If skin contact occurs remove contaminated clothing immediately. Wash the affected areas thoroughly with large amounts of water. If inhalation, eye contact or ingestion occurs, consult the MSDS for prompt action, and in all cases seek medical attention immediately.

3.4 Standard solutions for calibration of oxidation reduction potential (ORP) contain the following chemicals:

- potassium ferrocyanide trihydrate

- potassium ferrocyanide
- potassium chloride

Avoid inhalation, skin contact, eye contact, and ingestion. Avoid combining with the pH buffers and with any acids since cyanide may be released. Isolate the ORP solution. Do not dispose with other calibration solutions. If skin contact occurs, wash affected areas thoroughly with large amounts of water. Consult the Health and Safety Plan, and the MSDSs therein.

3.5 Standard solutions for calibration of dissolved oxygen contain sodium sulfite, cobalt chloride, manganese sulfate, alkali-iodide-azide, sulfuric acid, starch solution and sodium thiosulfate. Avoid inhalation, skin contact, eye contact, and ingestion. If skin contact occurs, wash affected areas thoroughly with large amounts of water. Consult the Health and Safety Plan, and the MSDSs therein.

## 4.0 Interferences

4.1 Each of the parameters measured with this procedure is subject to various interferences including cross-contamination, turbidity, aeration, and temperature fluctuations. Care must be taken to ensure that the instrument remains in a stable, controlled environment throughout the calibration and monitoring process; and that the conditions under which the samples are analyzed are the same as those under which calibration is conducted.

4.2 There must be no air bubbles lodged between the probe and probe guard.

4.3 All standards should be stored according to manufacturers' instructions.

## 5.0 Personnel Qualifications

5.1 All field samplers are required to take the 40-hour OSHA health and safety training course and annual 8-hour refresher courses prior to engaging in any field collection activities.

5.2 Prior to implementation of this procedure, the field sampler will be instructed by a person experienced with these procedures and will demonstrate to the field team leader the proper set-up, calibration, operation, and routine maintenance of the hand-held equipment, as well as an understanding of this procedure.

## 6.0 Equipment and Supplies

- Copy of the instrument manual and instrument specifications
- Copy of the project Health and Safety Plan and Sampling and Analysis Plan
- Thermometer (with NIST trace)
- pH Buffers of 4, 7, and 10
- Conductivity standards (concentration dependent upon expected field conditions)
- Zobell ORP calibration standard
- Zero Dissolved Oxygen Solution
- Deionized Ultra-Filtered (DIUF) Water

- YSI Sonde with attached pH, Conductivity, Dissolved Oxygen, and ORP probes with clear flow-through cell
- YSI 650 MDS Multiparameter Display System
- Sonde communications cable
- Winkler DO Kit
- Ring stand or similar capable of holding the sonde and flow-through cell upright during low-flow groundwater sampling
- Kimwipes or equivalent
- Gallon-size plastic freezer bags (e.g. Ziploc) to protect the MDS and the top of the Sonde from rain

## 7.0 Procedure

All instrument probes must be calibrated before they are used to measure environmental samples, and the calibration should be checked at the end of the sampling day or if any anomalous readings are obtained. All results should be recorded on the YSI Water Quality Calibration Log Sheet, presented in Attachment 1.

### 7.1 Set-up

7.1.1 Before performing any calibration procedure the sonde and display/logger must warm-up for at least 15 minutes.

7.1.2 During the warm-up period, set the sonde up on a ring stand.

7.1.3 Prior to calibration, all instrument probes on the sonde must be cleaned according to the manufacturer's instructions. Failure to perform this step can lead to erratic measurements. The probes must also be cleaned by rinsing with deionized water before and after immersing the probe in a calibration solution.

7.1.4 Check the calibration solutions for expiration dates and do not use expired standards.

7.1.5 The temperature of the standards should be as close to the temperature of the samples to be measured as is practical.

7.1.6 For each of the calibration solutions, provide enough volume so that the probe and the temperature sensor are sufficiently covered. Specific detail on the volume required for each sonde and calibration solution is provided on pages 2-29 and 2-30 of the YSI 6-Series Instrument Manual.

7.1.7 Check the display/logger to determine the battery level in the display/logger to see if new batteries are necessary.

7.1.8 Set up instrument display so that the following items are displayed:

- DO (%)
- ORP (mV)

- DO (mg/L)
- Cond. (µs/cm)
- Sp. Cond. (µs/cm)
- pH (Standard Units [S.U.])
- Temperature (°C)

7.2 Temperature

For instrument probes that rely on the temperature sensor (pH, dissolved oxygen/specific conductance, and ORP), the sonde temperature sensor needs to be checked for accuracy against a thermometer that is traceable to the National Institute of Standards and Technology (NIST). This accuracy check should be performed at least quarterly, and the date and results of the check kept with the instrument. Temperature checks will be checked by the rental company for rented units, and by the M&E equipment manager for M&E-owned units. Prior to mobilizing, obtain the date and results of the check from the equipment room manager or check the outside of the case for rental units. If the check has not been performed within the past three months, do not use the instrument. Document the date, results, and company that performed the check on the calibration log sheet or in the field logbook. In the event that verification is required, the procedure is presented below:

7.2.1 Fill a container with water and adjust the water temperature to a temperature below the temperature of the samples to be measured.

7.2.2 Place a thermometer that is traceable to the NIST into the water and wait for both temperature readings to stabilize.

7.2.3 Compare the two measurements. The instrument's temperature sensor must agree with the reference thermometer within the accuracy of the sensor (+/- 0.2°C). If the measurements do not agree, the instrument may not be working correctly and the manufacturer should be contacted.

7.2.4 Repeat the procedure using a container of water that has a temperature above that anticipated for the samples to be measured.

7.3 Dissolved Oxygen

Dissolved oxygen (DO) content in water is measured using a membrane electrode. The DO probe's membrane and electrolyte solution should be inspected for any damage or air bubbles prior to calibration. If air bubbles, nicks, or damage are present, replace the membrane according to manufacturer's suggestions. After changing the membrane, it is preferable to wait 12 hours before use to allow the membrane to equilibrate. If this is not possible, note this in the calibration log. YSI 6-Series DO probe be must calibrated using the calibration cup provided with the sonde. Calibration of the DO probe requires inputting the current barometric pressure. The YSI 650 display/logger has a barometer within the unit and automatically provides this during the calibration procedure. The barometric pressure for all units onsite should be checked for agreement between units, or checked using the onsite barometer. Other display/loggers do not supply the barometric pressure, and this must be obtained from an onsite barometer. Do not use barometric pressure obtained from meteorology reports as these are usually corrected to mean sea level.

Calibration is performed using 100% saturated air, and checked immediately after with a solution with zero dissolved oxygen. The calibration check at the end of the day uses both 100% saturated air and the zero dissolved oxygen solution. In addition, on a weekly basis when the meter is in use, compare DO concentrations measured by the probe to those measured using the Winkler method.

7.3.1 DO Calibration

7.3.1.1 Gently dry the temperature sensor and remove any water droplets from the DO probe's sensor membrane according to the manufacturer's instructions. Note that the evaporation of moisture on the temperature sensor or DO probe may influence the readings during calibration.

7.3.1.2 Place a small amount of water (<1/8") in the bottom of the calibration cup. Engage only one thread of the calibration cap onto the sonde so that the DO probe is readily vented to the atmosphere. Take care to avoid touching the oxygen membrane with the calibration cups and flow-cell. The DO probe and thermistor must not be in contact with the water. Keep the instrument in run mode and wait approximately 15 minutes for the air in the calibration cup to become water-saturated (100% humidity at atmospheric pressure) and the temperature to equilibrate. Set up the remaining instruments and solutions in the meantime.

7.3.1.3 When the temperature has stabilized, go to Calibrate mode - **Calibrate DO%**

7.3.1.4 Record the temperature on the calibration log. Check the barometric pressure reading on the YSI versus the barometer and other YSIs present. Enter the barometric pressure if correction is necessary. Record the barometric pressure on the calibration log. (Note: barometric pressures presented in meteorological reports are generally corrected to mean sea level. These are not useful for calibrating the sonde, which requires uncorrected barometric pressure).

7.3.1.5 When the DO% and temperature readings have stabilized for at least one minute, press **enter**. Record the number that appears on the screen. Record also the DO mg/L value.

7.3.1.6 Check the oxygen solubility at that pressure and temperature on Table 1 and record under "Std temp/pressure correction." The instrument DO reading should be comparable with the value on the table (within $\pm$0.2 mg/L). If not, recalibrate, or replace DO membrane.

7.3.1.7 Make up the zero DO solution by filling the calibration cap with DI water, adding approximately 1 gram of sodium sulfite to supersaturate the solution. Add a few crystals of the cobalt chloride (purple salt) and stir. There should be solids on the bottom of the cap. Screw the cap tightly onto the YSI. Water should leak out to indicate that there is no air around the probes. An open disposable sample cup may be used in place of the

calibration cap, however if check criteria are not met, the procedure must be repeated using the calibration cap as described.

7.3.1.8 Immediately after calibration, if the DO is ≤ 0.50 mg/L and ≥ 0.00 mg/L, record the value on the calibration log. If the number stabilizes at a value > 0.50 mg/L, or reads negative, and an open cup was used, repeat the procedure with the closed calibration cup. If an open cup was not used, change the DO membrane and repeat the calibration and check.

7.3.1.9 Remove the cap, and rinse the probes well with DI water. Blot the probes dry, carefully avoiding the DO membrane.

7.3.2 DO End-of-Day Check

7.3.2.1 Perform the calibration check using the 100% saturated standard.

7.3.2.1.1.1 Follow Steps 7.3.1.1 and 7.3.1.2.

7.3.2.1.1.2 Allow the DO% and temperature readings to stabilized for at least one minute. Record the number that appears on the screen. Record also the DO mg/L value.

7.3.2.1.1.3 Check the oxygen solubility at that pressure and temperature on the attached table and record under “Std temp/pressure correction.” The instrument DO reading should be comparable with the value on the table (within ±0.5 mg/L).

7.3.2.2 Perform the calibration check using the zero dissolved oxygen standard.

7.3.2.2.1.1 Follow Step 7.3.1.7.

7.3.2.2.1.2 The DO should be ≤ 0.5 mg/L, but not negative. If the DO is above criteria, make up a new zero DO standard and used a closed calibration cap if an open cup was used. Repeat the calibration check. If criteria are still not met, note the failed criteria and the readings that are impacted.

7.3.3 Winkler Method

7.3.3.1 Fill a 300-mL glass stoppered BOD bottle with sample water. Remember no bubbles.

7.3.3.2 Immediately add 2mL of manganese sulfate to the collection bottle by inserting the calibrated pipette just below the surface of the liquid. (If the reagent is added above the sample surface, you will introduce oxygen into the sample.) Squeeze the pipette slowly so no bubbles are introduced via the pipette.

7.3.3.3 Add 2 mL of alkali-iodide-azide reagent in the same manner.

7.3.3.4 topper the bottle with care to be sure no air is introduced. Mix the sample by inverting several times. Check for air bubbles; discard the sample and start over if any are seen. If oxygen is present, a brownish-orange cloud of precipitate or floc will appear. When this floc has settle to the bottom, mix the sample by turning it upside down several times and let it settle again.

7.3.3.5 Add 2 mL of concentrated sulfuric acid via a pipette held just above the surface of the sample. Carefully stopper and invert several times to dissolve the floc. At this point, the sample is "fixed" and can be stored for up to 8 hours if kept in a cool, dark place. As an added precaution, squirt distilled water along the stopper, and cap the bottle with aluminum foil and a rubber band during the storage period.

7.3.3.6 In a glass flask, titrate 201 mL of the sample with sodium thiosulfate to a pale straw color. Titrate by slowly dropping titrant solution from a calibrated pipette into the flask and continually stirring or swirling the sample water.

7.3.3.7 Add 2 mL of starch solution so a blue color forms.

7.3.3.8 Continue slowly titrating until the sample turns clear. As this experiment reaches the endpoint, it will take only one drop of the titrant to eliminate the blue color. Be especially careful that each drop is fully mixed into the sample before adding the next. It is sometimes helpful to hold the flask up to a white sheet of paper to check for absence of the blue color.

7.3.3.9 The concentration of dissolved oxygen in the sample is equivalent to the number of milliliters of titrant used. Each milliliter of sodium thiosulfate added in steps 6 and 8 equals 1 mg/L dissolved oxygen.

## 7.4 pH

The pH of a sample is determined electrometrically using a glass electrode. Choose the appropriate standards that will bracket the expected values at the sampling locations. A two or three-point calibration can be performed. Typically, a three-point calibration using standards pH 4, pH 7, and pH 10 will be required. A calibration check is performed immediately after calibration using the pH 7 standard and a criterion of ±0.05 S.U. A calibration check is also performed at the end of the day using the pH 7 standard and a criteria of 0.2 S.U..

### 7.4.1 pH Calibration

7.4.1.1 Allow the buffered samples to equilibrate to the ambient temperature.

7.4.1.2 Remove the calibration cap and clean all of the probes on the sonde with deionized water. Begin with pH 7. Wipe with Kimwipe and immerse all the probes except the DO probe in the 7 pH solution. Place enough pH 7 solution in the calibration cup to immerse the pH probe, reference junction, and thermistor. Return to **calibration mode**.

7.4.1.3 Scroll to pH on the calibration menu. Select **3-pt calibration**.

7.4.1.4 Enter the pH value based on the solution temperature when prompted for the first value, and press **enter**. The pH value adjusted for temperature is presented on the label of the buffer solution.

7.4.1.5 When value is stable for approximately 30 seconds, press **enter**, and record the number that appears on the screen. The display will indicate that the calibration has been accepted and will prompt the analyst to enter a second pH value.

7.4.1.6 Remove probes from solution. Rinse with DI water, wipe carefully, and put all probes in solution pH 4. Make sure that there is enough pH 4 buffer to immerse the pH probe, reference junction, and thermistor.

7.4.1.7 Enter the pH value based on the solution temperature when prompted for the second pH solution, press **enter**.

7.4.1.8 Allow at least one minute for temperature equilibration. When value is stable for at least 30 seconds, press **enter**, and record the number that appears on the screen.

7.4.1.9 Repeat steps 5, 6, and 7 for the pH 10 solution.

7.4.1.10 Press **enter** or **esc** to go to calibration menu.

7.4.1.11 Go to the run mode to perform a calibration check of the pH 7 solution. Rinse the probe and immerse in pH 7 solution. The reading should be within ± 0.05 pH units of the pH value adjusted for temperature. If not, recalibrate. Record the reading.

7.4.2 pH End-of-Day Check

7.4.2.1 Go to the run mode to perform a calibration check of the pH 7 solution.

7.4.2.2 Rinse the probe and immerse in pH 7 solution. Record the reading. The reading should be within ± 0.2 pH units of the pH value adjusted for temperature.

7.4.2.3 If not, record on the measurements impacted that the pH calibration check criterion was not met.

7.5 Conductivity

Conductivity is used to measure the ability of an aqueous solution to carry an electrical current. Specific conductance is the conductivity value corrected to 25°C. Note that the pH buffers are highly conductive and will adversely impact calibration of conductivity. Thoroughly rinse the probes after performing pH calibration, and then pre-rinse the probe with the conductivity solution to be used.

EPA recommends that conductivity be calibrated using standards that bracket the range of concentrations expected. Conductivities in groundwater frequently range below 1,000 µS/cm; however YSI does not recommend calibration with standards below 1,000 µS/cm because interference with the instrument from outside electrical noise (RF) may be a factor. Since the calibration for conductivity is a 1-point calibration, and expected conductivities will generally be less than 1,000 µS/cm, calibrate with the 1,000 µS/cm standard, and perform a check with a lower conductivity solution to bracket the range (e.g. 100 µS/cm). If an alternative check concentration is required to bracket the expected concentrations of site samples, the alternative concentration will be specified in the site-specific QAPP.

7.5.1 Conductivity Calibration

7.5.1.1 Allow the calibration standards to equilibrate to the ambient temperature.

7.5.1.2 Carefully rinse the probes in DIUF, then in the first conductivity solution to be used.

7.5.1.3 Immerse all probes except the DO probe completely in the conductivity calibration solution. Make sure that the thermistor is immersed, and the conductivity cell is immersed past the vent hole. Gently tap the side of the calibration cup to dislodge any air bubbles trapped inside the cell.

7.5.1.4 Scroll to **conductivity** on the screen, then select **specific conductance**. Select calibrate to **µS/cm**. Enter the conductivity value for the standard at 25ºC in µS/cm, which is the same as the specific conductance for the standard

7.5.1.5 Press **enter** and wait for the readings to stabilize. Press **enter**. Record the readings for specific conductivity in the calibration log. Do not exit conductivity.

7.5.1.6 **Do not** indicate “accept” when the calibration indicates “Out of Range.” Possible causes are incorrect entry, low level of solution, bubbles, or a bad probe. Attempt to recalibrate. If the problem persists, use another instrument. Return the instrument to the vendor or equipment room.

7.5.1.7 Perform a check of the calibration. Remove the probes from the solution. Rinse with the next conductivity solution. Immerse all probes except DO in the conductivity calibration solution. Allow the number to stabilize and record the values for specific conductivity in the calibration log. If the specific conductivity result is not within 5% of the value on the bottle, recalibrate. Remove probes from solution and rinse with DI water. Wipe dry.

7.5.2 Conductivity End-of-Day Check

7.5.2.1 Rinse the probes with the conductivity solution. Immerse all the probes except the DO probes in the conductivity calibration solution.

7.5.2.2 Allow the number to stabilize and record the values for conductivity and specific conductivity in the calibration log. If the specific conductivity result is not within 5% of the value on the bottle, note on the measurements obtained that the conductivity calibration check criteria were not met.

7.5.2.3 Remove the probes from solution and rinse with DI water. Wipe dry.

7.6 Oxidation Reduction Potential

ORP will be checked for accuracy, and will only be field calibrated if the calibration check fails criteria.

7.6.1 ORP Calibration

7.6.1.1 Switch to **run mode**. Gently mix the ORP solution and open the packet. Put all but the DO probe in the ORP solution. Allow to stabilize and record reading. If reading is not within ±10mV of the actual value corrected for temperature (see Table 2), proceed to 7.6.1.2.

7.6.1.2 Go to Calibration mode. Scroll to ORP and press **enter**. Enter ORP value (**corrected for temperature** - see above) and press **enter**. When the number is stable for 20 seconds, press **enter** and record the number. If instrument says "Out of Range," do not accept the value: Use a different instrument. If a different instrument is not available, record the number and note that it is not within limits.

7.6.2 ORP End-of-Day Check

7.6.2.1 Switch to **run mode**.

7.6.2.2 Gently mix the ORP solution and open the packet. Put all but the DO probe in the ORP solution.

7.6.2.3 Allow to stabilize and record reading. If reading is not within ±10mV of the actual value corrected for temperature (see table below), note on the measurements affected that the criterion for ORP check was not met.

7.7 Close up Instrument (After calibration and prior to mobilizing to the sampling location)

7.7.1 Replace clean cap over probes.

7.7.2 Select MDS Menu mode. Reset the parameters to the field sampling parameters:

- Time (24hr) – correct as needed
- pH (S.U.)
- specific conductivity (µs/cm)
- ORP (mV)
- Temperature (°C)
- DO (mg/L)

7.7.3 Shut off computer, and return to case

**8.0 Data and Records Management**

8.1 Calibration logsheets shall be used to document the details of instrument calibration and calibration checks.

8.2 The site logbook should be used to note when instrument calibration and instrument calibration checks were conducted, and should reference the calibration logsheets for details.

## 9.0 Quality Control and Quality Assurance

9.1 Quality Control Criteria are summarized in Table 2.

9.1.1 If a parameter is measured that lies outside of the range bracketed by the instrument calibration standards, the instrument must either be recalibrated using standards that bracket the value or a calibration check using a standard that brackets the value must be performed. If the standards are not available to bracket the result, the data must be qualified.

9.1.2 Readings measured by instruments that are subsequently found to be outside of criteria during the calibration check shall be documented on the sampling worksheet used to document the sample collection.

9.2 Pollution Prevention

9.2.1 Containers used to calibrate the probes shall be sized to use the smallest amount of standard possible but still accommodate all probes which need to be in the calibration solution such that they are adequately covered.

9.2.2 Conductivity and pH calibration solutions may be reused at the end of the day with caution if properly stored. However, a calibration check that reuses standard but does not meet criteria should be re-checked with fresh standard, and calibration should be conducted with fresh standards.

9.3 Waste Management

Unused calibration standards should be returned to the equipment room manager for proper disposal. Do not combine ORP standards with other standards since cyanide could be released.

**Attachment: YSI Water Quality Calibration Log**

**SOP NUMBER: 2600-150A**

# Operation/ Field Calibration of the Baseline BTX Model 1030A GC

**Date:** October 2004
**Revision Number:** 01
**Author:** Tony Sacco
**Discipline:** Air Toxics Monitoring

## 1.0 PURPOSE AND SCOPE

The purpose of this SOP is to provide a method for field personnel to operate and calibrate/ adjust the span response setting of the Baseline model 1030A gas chromatograph (GC) that is configured to speciate the BTX compounds benzene, toluene and the m, o, p-xylenes ( defined as Xylene).

This operation and calibration procedure assumes that the Model 1030A GC is installed in a real-time network where the analog output from each of the GC channels is sent to a Odessa Model 3260 data logger. The data logger converts the signals (0-10VDC) to engineering units. The engineering units are communicated to a desktop central computer by means of a telemetry system such as a spread spectrum or other wireless system

This SOP is intended for the use of individuals who have been trained in the task of calibration in general and in the calibration of this specific instrument, in particular.

## 2.0 RESPONSIBILITIES

**2.1** It is the responsibility of the project manager to make the proper training available to the qualified project field personnel.

**2.2** It is the responsibility of the project engineer to provide the training and guidance to field personnel prior to any field activity where this SOP is to be employed.

**2.3** It is the responsibility of the affected field personnel to read and understand this SOP and to also, read and understand the manufacturer's operation manual for the **Baseline, Model 1030A BTX Gas Chromatograph (GC)**.

## 3.0 REQUIRED MATERIALS

- Single pen strip chart recorder (0-10 VDC range) with the capability of a chart speed of 2 cm/min.
- Calibration gas mixture of benzene (approx. 1ppm), toluene (approx. 5 ppm), xylene (approx. 5 ppm).
- Electronic Calculator.
- Calibration form(s) (NJNG Calibration of Baseline GC).
- 10" adjustable wrench, 6" adjustable wrench.

- Laptop computer or data terminal (Optional).
- The manufacturer's operation manual for the Baseline, Model 1030A BTX Gas Chromatograph.

## 4.0 INSTRUMENT SPECIFICATIONS

- Dynamic Range: Benzene (0-2.00 ppm), Toluene (0-10.00 ppm), Xylene (0-10.00 ppm)
- Detection limits: 0.001 ppm, Benzene, Toluene, Xylene.
- Precision: 1% or 0.02 ppm
- Accuracy: +/- 1% of full scale
- Calibration: See section **6.0**
- Detector: PID 10.6 eV lamp
- Columns: packed
- Power: 115 VAC @ 60 Hz and 300 watts
- Operating conditions: 40-95 ºF (4-40 ºC); humidity, 10-85%, non-condensing.
- Carrier Gas: Helium containing <1ppm total hydrocarbons

## 5.0 CALIBRATION FREQUENCY

**5.1** A daily automatic span check is conducted for benzene, toluene and xylene. The span check is initiated through the data logger at each monitoring site and takes place during a time when there are no site activities.

**5.2** The site technician will conduct the following corrective actions on the basis of the nightly span checks results:

- **Routine QC Adjustment** ( section **6.0**)– if the span check error on any BTX channel is less than +/- 25% of full scale
- **QC Adjustment with Dynamic Calibration Verification** (section **7.0**) - if the span check error on any BTX channel is equal or greater than +/-25% of full scale

## 6.0 ROUTINE QC ADJUSTMENT

**6.1** Prior to going to the monitoring station that requires adjustment; fill out the top portion of the calibration data sheet "**Calibration of Baseline GC**". In order to determine the percent of Full Scale **(%FS)** that is expected for each of the compounds, use the following equation:

$$\%FS = \frac{cyl.ppm}{Span - ppm} \quad (100)$$

Where:

%FS = the expected % of full scale that is expected for the compound

*Cyl. ppm* = the concentration of the compound in the calibration gas cylinder (ppm). (**Note:** This information should be noted on a paper tag or a label directly on the cylinder bottle installed in the monitoring station.)

*Span-ppm* = the full-scale range of the GC for the compound (ppm). (See list below)

The Span-ppm for the BTX compounds are:

**Benzene = 2 ppm,**
**Toluene = 10 ppm**
**Xylene = 10 ppm.**

**6.2** Locate the monitoring station, verify that the Monitor System Unit # matches the station (site) # on the calibration data sheet or on the daily span check report.

**6.3** Verify the GC is in **Standby** mode, switch the display to the BTX channel required adjustment

**6.4** Un-lock the corresponding BTX channel potentiometer (pot), turn the pot clockwise or counter-clockwise until the display is equal to the corresponding expected value in % full scale (**D**) as indicated on the calibration data sheet. Go to Step 6.5. But if the pot has run out of adjustment, a coarse adjustment should be performed as follow:

**6.4.1** Adjust the pot to mid-scale ( 5.00), and then remove the cover of the GC chassis

**6.4.2** Locate the integrated control/output PCB inside the chassis, this PCB is mounted on the panel in the middle left hand side of the chassis and on the same side as the sample pump.

**6.4.3** Locate the 8 position DIP switches on the PCB. Record the current setting on calibration data sheet

**6.4.4** Turn on the next combination of switches to increase the effective gain ( refer to page 20 of the operation manual for the effective gain setting) (ie. Switch 4 on = effective gain X5, switches 5&6 on = effective gain X8.33, etc.)

**6.4.5** Repeat step **6.4** to fine tune the adjustment to the expected %of full scale.

**6.5** Lock the pot when the adjustment is complete and record the **After Cal** pot setting on the calibration data sheet

**6.6** Repeat step **6.4** and **6.5** for other BTX channels as necessary

**6.7** At the Main site, perform the following steps to activate the GC into speciation mode for analyzing the ambient sample and to reset the BTX integrated outputs to ambient condition.

**6.7.1** At the conclusion of a polling cycle press the **ESC** key of the computer terminal of the desktop PC (when the screen flashes several times) and the screen will display the **Main Menu** list.

**6.7.2** Select "**Communicate with DAU (SCADA)**" by using the arrow keys and move the cursor to appropriate box , Key in **X** and then press the **F1** key. Select the DAU # corresponding to the number on the shelter door of the GC that is to be calibrated (1-9) and press the **F1** key and then **F1** key again, the data logger responds with the specific DAU # indicating that it is in data collection mode and is logged in

**6.7.3** In data collection mode, key-in **A**; the data logger will respond with a sub-menu consisting of a listing of action items; enter a **1** ( start seq), when data logger prompts again; enter a **3** to activate sequence 3 of the data logger set up. (note: sequence 3 was designed to accomplish step **6.7** to reset the BTX integrated outputs to ambient conditions)

**6.8** Press **ESC** and **ESC** again to bring the desktop PC back to displaying the data screen.

**6.9** Press **Alt M** for a Marco screen , select " **Change Display to BTX and PM10**" Verify that when sequence **3** is complete, all BTX outputs are near ambient concentration levels.

**6.10** Press **Alt M** again for the Macro screen; select "**Change Display to TVOC and PM10** " to return monitor to the normal data display screen.

## 7.0 QC ADJUSTMENT WITH DYNAMIC CALIBRATION VERIFICATION

**7.1** Repeat steps **6.1** through **6.6**

**7.2** At the Main site, perform the following steps to activate the daily calibration sequence for the GC to verify the field QC adjustment.

**7.3** At the conclusion of a polling cycle on the desktop PC (when the screen flashes several times) and from data display screen, press the **ESC** key at the computer terminal and the screen will display the **Main Menu** list.

**7.4** Select "**Communicate with DAU (SCADA)**" by using the arrow keys and move the cursor to related the appropriate box , Key in **X** and then press the **F1** key. Select the DAU # corresponding to the number on the shelter door of the of the GC is to be calibrated (1-9) and press the **F1** key and then the **F1** key again, the data logger responds with the specific DAU # indicating that it is in data collection mode and is login

**7.5** In data collection mode, Key-in **A**, data logger will respond with a sub-menu, enter a **1** (start seq), when data logger prompts again, enter a **1** to activate sequence 1 of the data logger set up. (note: sequence 1 was designed for the daily calibration of the GC)

**7.6** Press **ESC** and **ESC** again to bring the desktop PC back to displaying data screen.

**7.7** When daily calibration sequence **1** is complete (the calibration sequence should be completed within 25 minutes), press **ESC** to return to the **Main Menu**,

**7.8** Select" **Generate Quick Look Report**" on **Main Menu** then **F1,** select the specific DAU #, and then **F1**

**7.9** Verify the date of the daily calibration report to be generated and then select a **Single Day** report.

**7.10** Key-in **X** on "**Calibration Report to a Printer".**

**7.11** Check and verify the start time on the report is correct

**7.12** scale. The QC adjustment is complete.

**7.13** Verify that the calibration result of all BTX channels is within +/- 20 % of the full If the result is more than +/- 20 % of full scale on any BTX channel, the GC should be removed for services and replaced with a backup unit.

## 8.0 DYNAMIC CALIBRATION AFTER MAINTENANCE SERVICE

This calibration procedure should be performed after trouble-shooting or maintenance service ( e,g cleaning and/or replacing the UV lamp or PID detector. Refer to page 16 of the Operation Manual for detailed maintenance procedure) and is recommended to be conducted in a temperature controlled environment such as inside the trailer located at the Main site. The 1030A GC should be removed from the monitoring location and set up inside the trailer.

**8.1** After the performing any maintenance services, re-connect the Helium carrier gas and the calibration gas cylinder to the GC

**8.2** Turn GC power on, verify the carrier gas is on and that the analyzer is in **standby** mode. Allow the GC to warm up at minimum of 1-2 hours or until the temperature reaches its set point.

**8.3** install a strip chart recorded and connect the chart recorder input leads to Pin 2(+) and Pin 10(-) on connector 1 at the rear panel of the GC.( **Note**: polarity of

the leads should be observed). Plug the recorder power cord into a power outlet. Confirm the recorder is getting power and the pen and chart advance is operating. The chart will move slowly at 2 centimeters per hour (one inch per hour). Set recorder signal input span to 0-10Vdc

**8.4** Repeat step **6.1** described above, determine the % full scale (D) for each BTX compound and fill out data sheet with required information

**8.4** Locate and press the **Auto** button on the GC followed by the **Clear** button on the lower right front panel of the Baseline GC.

**8.5** Put the 1030A GC **CAL** switch in the **ON** (up) position and confirm the recorder is attached and operating (responding to the GC). The display panel above the GC keypad will begin scrolling through the timing program similar to the program as indicated on Page 5 of the Model 1030A Analyzer Operation Manual. Observe that the RED **Stand-bye** lamp (located to the left of the display screen) goes out and that the GREEN **Analyze** lamp (located below the stand-bye lamp) comes on.

**7.6** Adjust the chart speed of the recorder to obtain a smooth chromatogram showing good separation of the BTX compounds. Allow the GC to complete at least 3 cycles or until the peak heights from two consecutive cycles for each of the BTX compounds have stabilized. The heights should be approximately the same when observing the strip chart.

**8.6** After the peak heights have stabilized, record the **%FS** data from the GC display screen on the calibration data sheet.

**8.7** Release **AUTO** and depress **CLEAR** to stop the analysis

**8.8** Adjust the calibration potentiometer (pots), which are located below the display screen, to the expected % full scale for each of the BTX compounds (benzene is **CH1,** toluene is **CH2**, and xylene is **CH3**).
**Note**: The selector switch below the display screen must be set to the appropriate channel before it can be adjusted

**8.9** Record **yes** in the column marked **Cal. Adj** on the calibration data form

**8.10** At the conclusion of the calibration record the final potentiometer settings in the spaces marked **After cal.** on the calibration data form. Be sure to lock the pot(s) at the conclusion of the calibration

**8.11** Place the **CAL** switch on the GC to the middle position, depress **AUTO** and then **CLEAR** to switch into speciation and allow the GC to go through two cycles without span gas to re-set the integrated output to ambient concentration.

**8.12** The GC is ready for monitoring service

.

## 9.0 DOCUMENTATION

Make certain to document all calibrations along with comments in the field station log. Return all equipment and tools to the proper locations.

## 10.0 QUALITY ASSURANCE

All calibration documentation will be reviewed by the project engineer. Quarterly audits of the GCs will be conducted by the project quality assurance officer.

Standard Operating Procedure

# Changing the BTX Span Value(s) for an Air Monitoring System

## 1.0 Scope and applicability

**1.1** This Standard Operating Procedure (SOP) defines methods by which technicians may change the values for the benzene, toluene and xylenes (BTX) span values for the gas chromatograph/photoionization detector (GC/PID) instruments installed at a fenceline air monitoring site.

**1.2** This SOP applies to those situations when a new cylinder of BTX is being installed at a monitor location. The method in this SOP is used to change the database so that the designated values for the BTX calibration reflect new span concentrations.

**1.3** This SOP is to be utilized to conduct the work identified in the title of this SOP. In the event the Project Manager or Project Team determines that the protocols and procedures listed in this SOP are not applicable to the project, there is the option to either adapt this SOP or to develop a site-specific SOP to more closely match the requirements of the project. Refer to SOP 1011, Preparation and Control of Standard Operating Procedures, for SOP modification and Project Operating Procedure (POP) development procedures.

## 2.0 Health and safety considerations

**2.1** The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, will be addressed in the site specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the ENSR Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

## 3.0 Interferences

- Employing calibration gases that have not been properly certified may cause data to be rejected.
- Calibration gases used outside of the operating range of the monitoring system may cause data to be rejected.
- Leaks in the GC/PID pneumatics may lead to erroneous data.

## 4.0 Equipment and materials

- BTX calibration cylinder.
- Calibration gas in the appropriate range for the monitoring program under test.
- A tool kit that includes several adjustable wrenches.

# 5.0 Procedures

**5.1** As soon as the pressure in any BTX calibration cylinder declines below 500 psig the field technician should inform the project engineer so that new calibration gas can be ordered. The cylinder pressure may be observed on the cylinder regulator pressure gage which is the gage that is closer to the cylinder. In order to read the pressure, the cylinder supply valve must be turned on.

**5.1.1** The BTX calibration cylinder should be replaced when the gas pressure falls below 100 psig.

**5.1.2** The procedure below should be followed in order to replace a BTX calibration cylinder.

1. Shut off the cylinder supply valve.
2. Shut off the regulator supply valve.
3. Use a 6" adjustable wrench to remove the fitting that connects the Teflon line to the GC.
4. Slowly bleed any pressure that may remain in the regulator by opening the regulator supply valve. Be sure to shut the valve after the regulator has been bled.
5. Use a 10" adjustable wrench to remove the regulator from the cylinder.

**NOTE: THE THREAD ON THE FITTING IS LEFTHAND. IN ORDER TO REMOVE IT THE FITTING MUST BE TURNED CLOCKWISE.**

6. Connect the regulator to the new BTX cylinder using a 10" adjustable wrench. The fitting must be turned **counterclockwise**.
7. Reconnect the fitting for the Teflon® line to the regulator. Make sure that the regulator output valve is shut.
8. Turn on the cylinder supply valve. The cylinder pressure gage should register approximately 2000 psig. If the gage registers less than 1500 psig, inform the project engineer. You may still use the cylinder.
9. Use Snoop liquid to identify whether there are any leaks at any of the thread connections. This will be obvious by the appearance of bubbles where the Snoop has been applied.
10. Turn on the regulator supply valve and set the pressure to approximately 20 psig.

**5.2** Once the new cylinder has been installed and leak checked, the new span values for the BTX compounds should be input to the computer at the main site.

**5.2.1** From the dual data screen key in **ESC**.

**5.2.2** Scroll down to the line that reads "Perform Operator Functions" and key in **F1**.

**5.2.3** Select the option that indicates "Change Expected Calibration Factors" and key in **F1**.

**5.2.4** Select the monitor number where the BTX calibration values are to be changed and key in **F1**.

**5.3** Select the parameter (benzene, toluene or xylene), key in **F1** and enter the new expected span value (the expected span values for each BTX compound is printed on the certification tag on the calibration cylinder).

**5.4** Key in **ESC** and repeat steps 5.2.2 - 5.2.5.

**5.5** When all the required span values have been modified, key in **ESC, ESC** to return to the dual data screen.

# 6.0 Quality assurance / quality control

**6.1** Calibrations should always leave the analyzer operating within ± 5.0% of the reference calibrator at all calibration inputs.

**6.2** As soon as possible following calibration, the completed data form is to be submitted to the project manager or designee for review in accordance with ENSR's Senior Review Policy PP-9-0. Standards are reviewed for traceability and completeness. DAS and strip chart readings are to be reviewed for agreement and completeness. Calculations, standard conditions, correction factors, project identification, and other data should be reviewed for accuracy, completeness and conformance to the relevant ENSR operational SOP and the project QA Plan.

# 7.0 Data and records management

**7.1** Unanticipated changes to the procedures or materials described in this SOP (deviations) will be appropriately documented in the project records.

**7.2** Records associated with the activities described in this SOP will be maintained according to the document management policy for the project.

# 8.0 Personnel qualifications and training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures should have read, and be familiar with, the requirements of this SOP.

**8.1.2** Technicians attempting the tasks in this SOP must be thoroughly trained to operate and calibrate the GC/PID being used.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this SOP.

**8.2.2** It is the responsibility of the project manager and project engineer to make this SOP available to field personnel and to ensure that the method described in this SOP is directly applicable to the task.

**8.2.3** It is the responsibility of the field technicians to read and follow this SOP at any time when a new BTX span cylinder is to be installed.

Project Operating Procedure

# Standard Operating Procedure for the Niton XL3t 600 XRF

## 1.0 Scope and Applicability

**1.1** This Project Operating Procedure (POP) provides the proper techniques for safely operating the Niton XL 3t 600 X-Ray fluorescence (XRF) analyzer for field screening of metals, primarily chromium, in soil. The procedure will permit in-situ analysis of soil samples for field decision making and will be used for delineation purposes during the remedial investigation. This procedure is not intended for submission of data to regulatory agencies; confirmatory analysis must be performed by a certified laboratory using EPA total metals methods.

**1.2** This procedure is to be used in conjunction with the site specific Field Sampling Plan. This procedure is intended to provide the necessary information for setting up and analyzing soil samples with the XRF analyzer and performing associated quality control procedures.

**1.3** This procedure is to be used in conjunction with the Niton XL 3t 600 XRF User's Guide. This procedure will provide the basic information for set up of the instrument and analysis of soil samples. However, certain custom functions are not covered in this procedure and must be referenced from the instruction manual.

**1.4** The method sensitivity or lower limit of detection depends on a number of factors including physical and chemical matrix effects and interelement spectral interferences; in-situ analysis and testing of bagged samples are considered field screening procedures. More accurate measurements using XRF are highly dependent on sample homogeneity; samples must be prepared by sieving and potentially grinding to a uniform particle size in order to achieve the most accurate results.

**1.5** In-situ XRF results alone are not acceptable for determining that a sample is below cleanup levels. In these cases XRF must be performed on a prepared (homogenized) sample and confirmed using a certified laboratory.

## 2.0 Health and Safety Considerations

**2.1** The health and safety considerations for the work associated with this POP, including both potential physical and chemical hazards, will be addressed in the site-specific Health and Safety Plan (HASP). In the absence of a site-specific HASP, work will be conducted according to the AECOM Health and Safety Policy and Procedures Manual and/or direction from the Regional Health and Safety Manager.

**2.2** Due to the dust generation anticipated from this procedure, field personnel will be required to don Level C personal protective equipment (PPE) for this procedure. Refer to the job safety analysis (JSA) for this activity in the site-specific HASP for more detail.

**2.3** The XRF analyzer contains an x-ray tube; when the x-ray tube is turned on by the user and the shutter is open, as during a measurement, the analyzer emits a directed radiation beam. The instrument should never be pointed at anyone or at any body part. **Never** point the analyzer into the air and perform a test. **Never** hold a sample in your hand and perform a test.

**2.4** Each field analyst must undergo training in safe use of the instrumentation by a manufacturer's representative prior to use of the XRF equipment. Protective shielding should never be removed by the analyst or any personnel other than the manufacturer. All maintenance other than that specifically listed in the operating manual must be performed by the manufacturer.

**2.5** Those operating XRF equipment must be aware of, and comply with, state-specific licensing requirements for the use of XRF analyzers (N.J.A.C 7:28-54.1). A copy of the license should be present with the instrument at all times and available upon request in an audit.

**2.6** A copy of the United States Department of Transportation (US DOT) compliance statement has been provided with each Niton instrument; this document should be kept in the analyzer case at all times.

**2.7** The analyst must comply with all safety requirements listed in the instrument specific operating manual.

## 3.0 Interferences

**3.1** Physical matrix effects can result from variations in the physical character of the sample. This includes variations in particle size, uniformity, homogeneity and surface condition. As a minimum every effort should be made to thoroughly mix and homogenize samples before analysis. The most accurate data will be obtained if samples are sieved and ground to a uniform particle size prior to testing.

**3.2** Moisture content of soils and sediments can impact analytical accuracy particularly if the sample is water saturated; moisture levels of 5-20% generally have a minimal impact on accuracy. If field data are to be compared with laboratory generated results, samples should be dried using a convection or toaster oven; a microwave should not be used due to the potential for arcing if metal fragments are present in the sample. Studies have also shown poor agreement between laboratory confirmatory analysis and field XRF data when microwave drying is used.

**3.3** Inconsistent positioning of the sample in front of the probe window can produce errors since the x-ray signal decreases as the distance from the radioactive source increases. The best results are obtained when the sample has a flat, smooth surface and the probe window is in direct contact with the surface.

**3.4** Chemical matrix effects can occur in soils contaminated with metals and result from spectral interferences (peak overlaps) or as x-ray absorption and enhancement phenomena. Peak overlaps occur when certain x-ray lines from different elements are close in energy; the degree to which these peaks can be resolved is dependent upon the instrument detector. Elevated levels of vanadium have been documented as a potential interference for chromium. Absorption occurs when one element tends to absorb the x-rays of a second element reducing the detector's measurement of the intensity of the second element. Less common

are interferences resulting from K/L, K/M, and L/M line overlaps; this interference can cause difficulty in detection of arsenic in the presence of high levels of lead.

**3.5** Ambient temperature changes can result in instrument drift. The analyst should review the instrument instructions for the optimal operating range of the instrument and assess the accuracy of instrument response through periodic analysis of blanks and QC check samples.

## 4.0 Equipment and Materials

**4.1** The following equipment and materials are required for sample analysis using this technique:

- Niton XL 3t 600 XRF
- Niton XL 3t 600 XRF User's Guide, Version 6.5
- U.S. DOT Compliance Statement and any state required licenses
- Battery charger and spare battery
- National Institute of Standards and Testing (NIST) certified standard reference material(s) (SRMs) or similar standards from the U.S. Geological Survey (USGS) or commercial sources.
- Reference standards and samples provided by the instrument manufacturer
- Blank sample of clean quartz, Teflon, or silicon dioxide
- Trowel for smoothing soil surface or collecting sample
- Plastic bags for collection and homogenization of soil samples.
- Field logbook and pen
- Level C PPE
- Camera (optional)

## 5.0 Procedures

**5.1** Initial Setup

**5.1.1** Don the Level C PPE as instructed in the site-specific HASP.

**5.1.2** To turn on the analyzer depress the on/off/escape button on the control panel for 10 seconds; the start screen will appear and begin a 10 second countdown. When the log on screen appears, press anywhere on the screen to continue. Acknowledge the radiation warning by pressing "Yes" and enter the security code for the device.

**5.1.3** Confirm that the date/time display is correct. Refer to the Niton XL3t 600 User's Guide for specific instructions on navigation through the menu. If the instrument has been turned off for more than 30 minutes allow a 10 minute warm-up period before calibration. Select Calibrate and Test and press Clear/Enter to begin the self calibration; when the instrument beeps the calibration is complete and the instrument is ready for use.

**5.1.4** For the purposes of in-situ measurements, the instrument will be operated in the Standard Soil Mode. Select Standard Soil Mode from the Bulk Analysis Menu. Calibrate the instrument using the soil standards supplied by Niton immediately after the instrument completes self-calibration. The standards should be tested every 1- 2 hours during the analysis day and at the conclusion of testing for the day to ensure that no drift has occurred. All calibration procedures and the results of standard check samples must be recorded in the XRF logbook. Until control limits specific to the XRF unit being used are established control limits of ± 20% of the true value should be used.

**5.1.5** The Niton XL3T 600 offers six modes of operation for soil samples. It is expected that the Easy Trigger method will be used for in-situ measurements. Using this technique the measurement window is placed against the sample and the trigger is pulled once to initiate the analysis. The instrument constantly checks the backscatter measurements to determine if a sample is against the measurement window and will shut off any radiation directed through the window if it determines there is no sample present.

**5.1.6** The analyzer will display the results screen throughout the duration of the reading; once the reading is complete, the screen will display the final results of the measurement.

**5.2** Sample screening may be performed by holding the probe directly on the soil or on a bagged sample. Clean the measurement window between samples using a cotton swab.

**5.2.1** Remove any obviously non-representative materials such as leaves, vegetation, roots, or concrete from the sample; use caution that COPR related materials are not removed from the sample. Finer and more homogeneous material will yield more accurate results. Increased accuracy can be gained by loosening the soil and letting it dry in the sun prior to testing. The soil sample should not be saturated with water; the XRF technique will generally not produce reliable results if ponded water exists on the surface.

**5.2.2** Use a trowel to level the surface of the soil. Hold the XRF in one hand and place the instrument window flush against the surface of the sample to be tested. The four LED lights on the screen will flash to indicate the initiating preconditions have been met (see page 1-45 of the User's Guide); however as a safety precaution the x-ray tube will not turn on immediately and no reading will begin for approximately 0.5 seconds. Watch the display screen to determine when the test is complete; a typical test will take 30-60 seconds. To end the test simply release the trigger mechanism.

**5.2.3** If direct measurement of the sample is not possible, samples may be placed in plastic bags and analyzed without preparation. However, since the measurement is made through a plastic bag, test results can be 5-10% lower than those obtained by direct measurement. Place 50-100g of soil in a clean zipper locking bag (approximately 1-mil thick polyethylene bag is recommended) removing any obviously non-representative material. Mix the sample thoroughly by kneading the bag and flatten the bag of soil to form uniform layer of approximately 0.5 inch thickness. Place the XRF flat against the bag and take a measurement as described in Section 5.2.2. ***Do not hold the bag in your hand during testing.***

**5.3** Download the stored data and spectra to a computer or directly to a database; erase the stored data from the XRF once you have confirmed that all results have been successfully downloaded. ***Do not attempt to take measurements while downloading readings, this will generate an error requiring a system reset and may corrupt stored readings.***

**5.4** Routine maintenance procedures include cleaning and replacement of the measurement window.

**5.4.1** Keep the transparent measurement window covering the analysis window clean. Clean the measurement window gently with a cotton swab. Clean the body of the analyzer with a soft cloth. The touch screen may be cleaned using a lens cleaning solution with a soft cloth; water should not be used. Never use detergents or solvents on any portion of the analyzer or immerse the analyzer in water.

**5.4.2** If the measurement window becomes frayed, ripped, or contaminated with metal particulates, replace it with a new window. The User's Guide provides part numbers and instructions for replacement of the windows.

**5.4.3** All other maintenance must be performed by an authorized Niton service center. The instrument must be transported and stored in its padded carrying case when not in use.

## 6.0 Quality Assurance / Quality Control

**6.1** An energy calibration check should be run at the start of each day of sampling. This check confirms that the characteristic x-ray lines are stable and instrument drift is not occurring. This also provides a gain check if the ambient temperature fluctuates significantly. This test must be run at the start of each day, when the batteries are changed, when the instrument is shut down, and at the end of each day. This procedure should also be run any time the operator believes that drift is occurring during analysis.

**6.2** A blank consisting of silicon dioxide or a Teflon or quartz block must be run at the beginning and end of each day of analysis and after every 20 samples or every hour of operation during the day or at any time the analyst suspects contamination in the analytical system.

**6.3** An independent standard must be used to verify the accuracy of the instrument and confirm its stability and consistency for the analyte of interest. NIST, USGS or commercial standards

may be used. The standard check must be performed at the beginning and end of each analysis day and after every 20 samples or hour of operation during the day. If the measured value falls outside the acceptance range the check sample must be reanalyzed; if it is still outside the acceptance range the instrument must be recalibrated and any samples analyzed since the previous acceptable calibration check must be reanalyzed.

**6.4** At least one sample in each set of 20 must be analyzed in duplicate to assess measurement precision. Relative percent difference for duplicates should be ≤ 30%.

**6.5** The field forms and field notes generated from this procedure will be reviewed by the sampling team leader, project manager, or designee. All quality control results must be downloaded to project computer files along with sample data. Any deviations from this SOP, problems encountered during the analysis and corrective actions taken must be documented in the field records.

## 7.0 Data and Records Management

**7.1** Unanticipated changes to the procedures or materials described in this POP (deviations) will be appropriately documented in the project records.

**7.2** All data and spectral files must be backed up onto a computer on a regular basis. Any deviations from this POP or problems encountered during the analysis must be documented in a field log book which is dedicated to the XRF analyzer.

**7.3** Records associated with the activities described in this POP will be maintained according to the specific document management policy for the project.

## 8.0 Personnel Qualifications and Training

**8.1** Qualifications and training

**8.1.1** The individual executing these procedures must have read, and be familiar with, the requirements of this POP.

**8.1.2** Sampling personnel must be health and safety certified as specified by Occupational Safety and Health Administration (OSHA) 29 CFR 1910.120(e)(3)(i) to work on sites where hazardous materials may be present.

**8.1.3** Each person who performs this procedure will undergo training offered by the manufacturer such that the procedure is performed in a consistent manner and all safety procedures are followed.

**8.1.4** Individual states and countries have specific regulations and guidelines for the use of X-ray tube devices that produce ionizing radiation. For New Jersey site work, the licensing requirements outlined in N.J.A.C. 7:28-54.1 must be met prior to the start of site work.

**8.2** Responsibilities

**8.2.1** The project manager is responsible for providing the project team with the materials, resources and guidance necessary to properly execute the procedures described in this POP.

**8.2.2** The individual performing the work is responsible for implementing the procedures as described in this POP and any project-specific work plans.

# Appendix C

# Required Preservation, Container and Maximum Holding Times

# Appendix C-1: Required Preservation, Container, and Maximum Holding Times for Solid and Aqueous Samples

## Table 2.2 Required Preservation, Container, and Maximum Holding Times for Drinking Water Samples, Except Radiochemical Parameters

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| Total Coliform Finished Drinking Water | Cool 4°C, 0.008% sodium thiosulfate ($Na_2S_2O_3$) | P or G | 30 hours |
| Heterotrophic Plate Count Finished Drinking Water | Cool 4°C, 0.008% $Na_2S_2O_3$ | P or G | 8 hours |
| Total Coliform Source Water | Cool 4°C, 0.008% $Na_2S_2O_3$ | P or G | 8 hours |
| Fecal Coliform Source Water | Cool 4°C, 0.008% $Na_2S_2O_3$ | P or G | 8 hours |
| Cryptosporidium | Cool 0-8°C, No Freezing | LPDE Cubitainer | Elution must begin within 96hrs of sampling[14] |
| Giardi cysts | Cool 0-8°C, No Freezing | LPDE Cubitainer | Elution must begin within 96hrs of sampling[14] |
| Alkalinity | Cool 4°C | P or G | 14 days |
| Antimony | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Arsenic | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Asbestos | Cool 4°C | P or G | Filter within 48 hours |
| Barium | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Beryllium | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Bromate | 50 mg/L Ethylenediamine (EDA) solution | P or G | 28 days |
| Bromide | None | P or G | 28 days |
| Cadmium | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Calcium | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Chlorate | 50 mg/L Ethylenediamine (EDA) solution | P or G | 28 days |
| Chloride | None | P or G | 28 days |
| Chlorite | 50 mg/L Ethylenediamine (EDA) solution Cool 4°C | P or G | 14 days |
| Chlorinated Hydrocarbons | Refrigerate at 4°C. After collection, Ascorbic acid | Glass with foil or Teflon®-lined cap | 14 days until extraction; 40 days after extraction |

Table 2.2 (continued) Required Preservation, Container, and Maximum Holding Times for Drinking Water Samples, Except Radiochemical Parameters

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| Chlorinated Pesticides | 80mg/L $Na_2S_2O_3$ if residual chlorine ($Cl_2$) is present, Cool 4°C | Glass with Teflon®-lined septum | 7 days until extraction; 14 days after extraction |
| Chlorinated Phenoxy Acids | 80mg/L $Na_2S_2O_3$ if residual chlorine ($Cl_2$) is present, Cool 4°C | Glass with Teflon®-lined septum | 14 days until extraction; 28 days after extraction |
| Chlorine Dioxide | None | P or G | Analyze Immediately |
| Chlorinated Acids | Refrigerate at 4°C after collection, Ascorbic acid | Glass with foil or Teflon®-lined cap | 7 days until extraction; 30 days after extraction |
| Chromium | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Copper | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Cyanide | NaOH to pH > 12, Cool 4°C, 0.6 g Ascorbic acid | P or G | 14 days |
| EDB/DBCP/1,2,3-TCP | Cool 4°C, 0.08% $Na_2S_2O_3$ | Glass with Teflon®-lined septum | extract: 14 days; 24 hours to analysis |
| Fluoride | None | Polyethylene only | 28 days |
| Free Chlorine Residual | None | P or G | Analyze Immediately |
| Lead | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Mercury | Conc. $HNO_3$ to pH < 2 | P or G | 28 days |
| N-Methyl-Carbamoyloximes N-Methyl-Carbamates | Monochloroacetic acid to pH 3, 80mg/L $Na_2S_2O_3$, Cool 4°C until storage, Store at -10°C | Glass with Teflon®-lined septum | 28 days at -10°C |
| Nickel | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Nitrate-Nitrate | Conc. $H_2SO_4$ to pH < 2; Cool 4°C | P or G | 28 days |
| Nitrate-N | Cool 4°C | P or G | 48 hours |
| Nitrite-N | Cool 4°C | P or G | 48 hours |
| Nitrogen- and Phosphorus-Containing Pesticides | 80mg/L $Na_2S_2O_3$ (if residual $Cl_2$) Cool 4°C | Glass (dark) with Teflon®-lined septum | 14 days until extraction; 14 days after extraction |
| o-Phosphate | Cool 4°C | P or G | 48 hours |
| Perchlorates | None Required | P or G | 28 days |

Table 2.2 (continued) Required Preservation, Container, and Maximum Holding Times for Drinking Water Samples, Except Radiochemical Parameters

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| Odor | Cool 4°C | P or G | 24 hours |
| Organic Compounds | If residual $Cl_2$ 40-50 mg sodium arsenite or sodium thiosulfate; if unchlorinated, 6 N HCl to pH < 2 | Glass with Teflon®-lined septum | 7 days until extraction; 30 days after extraction |
| Organohalide Pesticides and Commercial PCB Products (Arochlors) | 3mg $Na_2S_2O_3$ or 7uL $Na_2S_2O_3$ (0.04g/mL), Cool 4°C until analyzed | Glass with Teflon®-lined septum | If Heptachlor, 7 days until extraction; 40 days after extraction. If no extraction, analysis within 14 days |
| Ozone | None | G | Analyze Immediately |
| pH | None | P or G | Analyze Immediately |
| Selenium | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Silver | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Sodium | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| Sulfate | Cool 4°C | P or G | 28 days |
| Temperature | None | P or G | Analyze Immediately |
| Thallium | Conc. $HNO_3$ to pH < 2 | P or G | 6 months |
| TTHMs | $Na_2S_2O_3$ if residual $Cl_2$ and 6N HCl | Glass with Teflon®-lined septum | 14 days |
| Total Dissolved Solids | Cool 4°C | P or G | 7 days |
| Turbidity | Cool 4°C | P or G | 48 hours |
| Volatile Aromatic and Unsaturated Organic Compounds | 1:1 HCl to pH < 2 Cool, 4°C until analysis, Ascorbic acid | Glass with Teflon®-lined septum | 14 days |
| Volatile Halogenated Organic Compounds | 1:1 HCl to pH < 2 Cool, 4°C until analysis, Ascorbic acid | Glass with Teflon®-lined septum | 14 days |
| Volatile Organic Compounds | 1:1 HCl to pH < 2 Cool, 4°C until analysis, Ascorbic acid | Glass with Teflon®-lined septum | 14 days |

## Table 2.3 Required Preservation, Container, and Maximum Holding Times for Wastewater Samples and Solid/Hazardous Waste Samples (Aqueous Matrices), Except Radiochemical Parameters

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| **Bacterial Tests** | | | |
| Coliform (fecal) | Cool 4°C, 0.008% $Na_2S_2O_3$[1] | P, G | 6 hours |
| Coliform (total) | Cool 4°C, 0.008% $Na_2S_2O_3$[1] | P, G Cool | 6 hours |
| Fecal streptococci | Cool 4°C, 0.008% $Na_2S_2O_3$[1] | P, G | 6 hours |
| Enterococcii | Cool 4°C, 0.008% $Na_2S_2O_3$[1] | P, G (sterile) | 6 hours |
| Escherichia coli | Cool 4°C, 0.008% $Na_2S_2O_3$[1] | P, G (sterile) | 6 hours |
| Heterotrophic Plate Count | Cool 4°C, 0.008% $Na_2S_2O_3$[1] | P, G (sterile) | 8 hours |
| Salmonella sp. Bacteria | Cool 4°C | P, G (sterile) | 24 hours |
| Helminth Ova | Cool 4°C | P, G (sterile) | 24 hours |
| Enteric Viruses[13] | Cool 4°C | P, G (sterile) | 8 hours |
| **Toxicity Test** | | | |
| Acute or Chronic Toxicity | Cool 4°C | P, G | 36 hours[12] |
| **Inorganic Tests** | | | |
| Acidity, as $CaCO_3$ | Cool 4°C | P, G | 14 days |
| Alkalinity as $CaCO_3$ | Cool 4°C | P, G | 14 days |
| Aluminum-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Ammonia (as N) | Cool 4°C $H_2SO_4$ to pH < 2 | P, G | 28 days |
| Antimony-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Arsenic-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Barium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Beryllium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Biochemical Oxygen Demand | Cool 4°C | P, G | 48 hours |
| Boron-total[3] | $HNO_3$ to pH < 2 | P,G | 6 months |
| Bromide[3] | None required | P, G | 28 days |
| Cadmium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Calcium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Carbonaceous Biochemical Oxygen Demand | Cool 4°C | P, G | 48 Hours |

Table 2.3 (continued) Required Preservation, Container, and Maximum Holding Times for Wastewater Samples and Solid/ Hazardous Waste Samples (Aqueous Matrices), Except Radiochemical Parameters

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| Chemical Oxygen Demand (COD) | Cool 4°C $H_2SO_4$ to pH < 2 | P, G | 28 days |
| Chloride | None required | P, G | 28 days |
| Chlorine total residual (TRC) | None required | P, G | Analyze Immediately |
| Chromium VI (dissolved) | Cool 4°C | P, G | 24 hours |
| Chromium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Cobalt-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Color | Cool 4°C | P, G | 48 hours |
| Copper-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Cyanide-total[3] | Cool 4°C, NaOH to pH > 12,0.6g ascorbic acid | P, G | 14 days (24 hours when sulfide is present)[2] |
| Cyanide amenable to chlorination[3] | Cool 4°C, NaOH to pH > 12,0.6g ascorbic acid | P, G | 14 days (24 hours when sulfide is present)[2] |
| Fluoride | None required | Polyethylene only | 28 days |
| Gold-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Hardness-total as $CaCO_3$ | $HNO_3$ to pH < 2 $H_2SO_4$ to pH < 2, | P, G | 6 months |
| Hydrogen ion (pH) | None required | P, G | Analyze Immediately |
| Iridium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Iron-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Kjeldahl & Organic Nitrogen | Cool 4°C, $H_2SO_4$ to pH < 2 | P, G | 28 days |
| Lead-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Magnesium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Mercury-dissolved[11] (does not include methyl mercury) | 5mL/Lof 12 N HCl or 5mL/L of 12 N BrCl Cool 4°C | Fluoropolymer with fluoropolymer or fluoropolymer lined cap | 28 days |
| Mercury-dissolved[11] (includes methyl mercury) | 5mL/L of 12 N HCl Cool 4°C | Fluoropolymer with fluoropolymer or fluoropolymer lined cap | 28 days |
| Mercury-total[3] | $HNO_3$ to pH < 2 | P, G | 28 days |
| Mercury-total[11](does not include methylmercury) | 5mL/L of 12 N HCl or 5 mL/L of 12 N BrCl | Fluoropolymer with fluoropolymer or | 28 days |

Table 2.3 (continued) Required Preservation, Container, and Maximum Holding Times for Wastewater Samples and Solid/ Hazardous Waste Samples (Aqueous Matrices), Except Radiochemical Parameters

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| | Cool 4°C | fluoropolymer lined cap | |
| Mercury-total[11] (includes methylmercury) | 5mL/L of 12 N HCl Cool 4°C | Fluoropolymer with fluoropolymer or fluoropolymer lined cap | 28 days |
| Molybdenum-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Nickel-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Nitrate (as N) | Cool 4°C | P, G | 48 hours |
| Nitrate-Nitrite(as N) | Cool 4°C, $H_2SO_4$ to pH < 2 | P, G | 28 days |
| Nitrite (as N) | Cool 4°C | P, G | 48 hours |
| Oil and grease | Cool 4°C HCl or $H_2SO_4$ to pH < 2 | G | 28 days |
| Organic carbon-total (TOC) | Cool 4°C, HCl or $H_2SO_4$ to pH < 2 or phosphoric acid | P, G | 28 days |
| Orthophosphate (as P) | Filter Immediately, Cool 4°C | P, G | 48 hours |
| Osmium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Oxygen dissolved (probe) | None Required | Glass bottle and top | Analyze Immediately |
| Oxygen dissolved (Winkler) | Fix on site and store in dark | Glass bottle and top | 8 hours |
| Palladium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Petroleum Hydrocarbons | HCl to pH 2 | G | 7 days |
| Phenols | Cool 4°C, $H_2SO_4$ to pH < 2 | G only | 28 days |
| Phosphorus (elemental) | Cool 4°C | G | 48 hours |
| Phosphorus-total | Cool 4°C, $H_2SO_4$ to pH < 2 | P, G | 28 days |
| Platinum-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Potassium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Residue-total | Cool 4°C | P, G | 7 days |
| Residue-filterable (TDS) | Cool 4°C | P, G | 7 days |
| Residue-nonfilterable (TSS) | Cool 4°C | P, G | 7 days |
| Residue-settleable | Cool 4°C | P, G | 48 hours |
| Residue-volatile | Cool to 4°C | P, G | 7 days |
| Rhodium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Ruthenium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |

Table 2.3 (continued) Required Preservation, Container, and Maximum Holding Times for Wastewater Samples and Solid/ Hazardous Waste Samples (Aqueous Matrices), Except Radiochemical Parameters

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| Salinity | Cool 4°C | G | 28 days |
| Selenium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Silica-dissolved | Cool 4°C | P | 28 days |
| Silver-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Sodium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Specific conductance | Cool 4°C | P, G | 28 days |
| Sulfate | Cool 4°C | P, G | 28 days |
| Sulfide | Cool 4°C, add zinc acetate & NaOH to pH > 9 | P, G | 7 days |
| Sulfite | None required | P, G | Analyze Immediately |
| Surfactants | Cool 4°C | P, G | 48 hours |
| Temperature | None required | P, G | Analyze Immediately |
| Thallium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Tin-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Titanium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Turbidity | Cool 4°C | P, G | 48 hours |
| Vanadium-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |
| Zinc-total[3] | $HNO_3$ to pH < 2 | P, G | 6 months |

| Monuron-TCA | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Nuburon | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Parathion methyl | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Parathion ethyl | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| PCNB | Cool 4°C,pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Perthane | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Prometron | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Prometryn | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Propazine | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Propham | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Propoxur | Cool 4°C,pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Secbumeton | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Siduron | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |

Table 2.3 (continued) Required Preservation, Container, and Maximum Holding Times for Wastewater Samples and Solid/ Hazardous Waste Samples (Aqueous Matrices), Except Radiochemical Parameters

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| Simazine | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Strobane | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Swep | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| 2,4,5-T | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| 2,4,5-TP (Silvex) | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Terbuthylazine | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Toxaphene | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |
| Trifluralin | Cool 4°C, pH 5-9[10] | Glass, Teflon®-lined cap | 7 days until extraction; 40 days after extraction |

## Table 2.6 Required Preservation, Container and Maximum Holding Times for Solid/Hazardous Waste Samples (Soils, Liquids, Sediments, Sludges, and Ambient Air)

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| Volatile Organics for soil/ sediment, and sludge | Cool 4°C | Glass Teflon®-lined cap | 14 days |
| Volatile Organics (Non-Aqueous sample) | Cool 4°C, dark | Encore™ or equivalent field core sampling/ storage containers & 60 ml septum sealed glass vial | Transfer immediately upon receipt to methanol and sodium bisulfate solution, analyze within 14 days |
| Volatile Organics (Non-Aqueous sample) | Cool 4°C, dark | Field preserved vials methanol & sodium bisulfate Glass, 40 ml vial stir bar [sodium bisulfate only], septum sealed glass vial & 60 ml septum sealed glass vial | 14 days |
| Volatile organics in liquid samples | Cool 4°C, if residual $Cl_2$ add $Na_2S_2O_3$ and HCl to pH < 2 | Glass, Teflon®-lined cap | 14 days |
| Acrolein and Acrylonitrile in liquid samples | Cool 4°C Adjust to pH 4-5 | Glass, Teflon®-lined cap | 14 days |
| Semivolatile organics/ organochlorine pesticides/ PCBs and herbicides for soil/sediment, and sludge | Cool 4°C | Glass, Teflon®-lined cap | 14 days until extraction; 40 days after extraction |
| Semivolatile organics/ organochlorine pesticides/ PCBs and herbicides for concentrated waste samples | Cool 4°C | Glass, Teflon®-lined cap | 14 days until extraction; 40 days after extraction |
| Metals except Cr VI and Hg (total) for liquid samples | Cool 4°C, $HNO_3$ to pH < 2 | P, G | 6 months |
| Metals except Cr VI and Hg (dissolved) for liquid samples | Cool 4°C, Filter on-site $HNO_3$ to pH < 2 | P, G | 6 months |
| Metals except Cr VI and Hg (suspended) for liquid samples | Cool 4°C Filter on-site | P, G | 6 months |

Table 2.6 (continued) Required Preservation, Container and Maximum Holding Times for Solid/Hazardous Waste Samples (Soils, Liquids, Sediments, Sludges, and Ambient Air)

| Parameter | Preservation | Container | Maximum Holding Time |
|---|---|---|---|
| Metals except Cr VI and Hg for solid samples | Cool 4°C | P, G | 6 months |
| Chromium VI for solid samples | Cool 4°C | P, G | 30 days to digestion; analysis 168 hours after digestion |
| Chromium VI for liquid samples | Cool 4°C | P, G | 24 hours |
| Mercury (total) for liquid samples | $HNO_3$ to pH < 2 | P, G | 28 days |
| Mercury (dissolved) for liquid samples | Filter on-site $HNO_3$ to pH < 2 | P, G | 28 days |
| Mercury (total) for solid samples | Cool 4°C | P, G | 28 days |
| **Ambient Air Analysis** | | | |
| TO-15 Volatile Organics in Specially Prepared Canisters – GC/MS | None | Specially prepared canisters | 30 days from sample collection |
| TO-17 Volatile Organics in Ambient Air using Active Sampling onto Sorbent Tubes | Cool ≤4°C after sample collection and in refrigeration unless samples are analyzed the same day of collection. The samples must be stored in an organic solvent free environment. Small packages of activated charcoal/silica gel must be with each shipment container of multiple tubes. | Sorbent Tubes | 30 days from sample collection; except 7days if limonene, carene, labile sulfur, bischloromethylether or nitrogen containing volatiles |

## Table 2.7 Required Preservation, Container and Maximum Holding Times From VTSR for CERCLA-CLP Aqueous and Non-Aqueous Samples

| Parameter | Preservation | Container | Maximum Holding Time From Validated Time of Sample Receipt (VTSR) |
|---|---|---|---|
| Volatile Organics (Aqueous) | Cool 4°C, dark 0.08% $Na_2S_2O_3$ if residual $Cl_2$ | Glass, white polypropylene or black phenolic plastic screw Teflon®-lined septum | 10 days |
| Volatile Organics (Non-Aqueous) | Cool 4°C, dark | Glass, polypropylene cap, white Teflon® liner | 10 days |
| Volatile Organics (Non-Aqueous) | Cool 4°C, dark | Encore™ or equivalent field core sampling/ storage container & 60 ml septum sealed glass vial | Transfer immediately upon receipt to methanol and sodium bisulfate solution analyze within 10 days |
| Volatile Organics (Non-Aqueous) | Cool 4°C, dark | Field preserved vials methanol & sodium bisulfate glass, 40 ml vial stir bar [sodium bisulfate only], septum sealed glass vial & 60 ml septum sealed glass vial | 10 days |
| Pesticide/PCBs | Cool 4°C, dark | Amber Glass, white polypropylene or black phenolic, baked polyethylene cap | Extraction Aqueous: continuous liquid-liquid extraction must be started within 5 days, Non-Aqueous: 10 days analysis, 40 days from VTSR |
| Polychlorinated Dibenzo-p-Dioxins (PCDDs) and Dibenzofurans (PCDFs) (Non Aqueous) | Cool 10°C, dark | Amber Glass, white polypropylene or black phenolic, baked polyethylene cap | Extraction: 30 days from VTSR, analysis 45 days from extraction |

Table 2.7 (continued) Required Preservation, Container and Maximum Holding Times From VTSR for CERCLA-CLP Aqueous and Non-Aqueous Samples

| Parameter | Preservation | Container | Maximum Holding Time From Validated Time of Sample Receipt (VTSR) |
|---|---|---|---|
| Polychlorinated Dibenzo-p-Dioxins (PCDDs) and Dibenzofurans (PCDFs) (Aqueous) | Cool 4°C, dark | Amber Glass, white polypropylene or black phenolic, baked polyethylene cap | Extraction: 30days from VTSR, analysis: 45 days from extraction |
| Polychlorinated Dibenzo-p-Dioxins (PCDDs) and Dibenzofurans (PCDFs) (Fish and Tissue Samples) | Cool 4°C, dark until prepared then-10°C until analysis | Wrapped in aluminum foil in field | Extraction: 1 year from VTSR. Once thawed, must be analyzed within 24 hours. Analysis: 45 days from extraction |
| Cyanide, total amenable to chlorination | Aqueous - 0.6g ascorbic acid if residual $Cl_2$, NaOH to pH>12, cool 4°C, $CaCO_3$ in presence of sulfide | Plastic bottle, plastic cap, plastic liner | 14 days |
| Metals except Hg (Aqueous) | $HNO_3$ to pH<2, cool 4°C, until analyzed | Plastic bottle, plastic cap, plastic liner | 180 days |
| Metals – Dissolved except Hg (Aqueous) | Field filter 0.45 µm pore diameter filter, rinse bottle with sample then immediately $HNO_3$ to pH<2, cool 4°C until analyzed | Plastic bottle, plastic cap, plastic liner | 180 days |
| Metals except Hg (Non-Aqueous) | Cool 4°C until analyzed | Flint glass bottle, black phenolic cap, polyethylene liner | 180 days |
| Hg (Aqueous) | $HNO_3$ to pH<2, Cool, 4°C until analyzed | Plastic bottle, plastic cap, plastic liner | 26 days |
| Hg – Dissolved (Aqueous) | Field filter 0.45 µm pore diameter filter, rinse bottle with sample immediately, $HNO_3$ to pH<2, Cool, 4°C until analyzed | Plastic bottle, plastic cap, plastic liner | 26 days |
| Hg (Non-Aqueous) | $HNO_3$ to pH<2, Cool, 4°C until analyzed | Flint glass bottle, black phenolic cap, polyethylene liner | 28 days |

Table 2.7 (continued) Required Preservation, Container and Maximum Holding Time From VTSR for CERCLA-CLP Aqueous and Non-Aqueous Samples

| Parameter | Preservation | Container | Maximum Holding Time From Validated Time of Sample Receipt (VTSR) |
|---|---|---|---|
| Cyanide (Aqueous) | 0.6g ascorbic acid if residual $Cl_2$ NaOH to pH>12, cool 4°C until analyzed | Plastic bottle, plastic cap, plastic liner | 14 days |
| Cyanide (Non-Aqueous) | Cool 4°C, until analyzed | Plastic bottle, plastic cap, plastic liner | 14 days |
| Low Level Volatile Organics | Cool 4°C, dark, 0.008% $Na_2S_2O_3$ | Glass, black phenolic or white polypropylene screw cap, Teflon®-lined septum | 7 days |
| Low Level Semi-volatile Organics | Cool 4°C, dark | White polypropylene or black phenolic, baked polyethylene cap | Extraction: continuous extraction must be started within 5 days of VTSR. Analysis: 40 days from start of extraction |
| Low Level Pesticides/PCBs Organics | Cool 4°C, dark | Amber glass, white polypropylene or black phenolic, baked polyethylene cap | Extraction: continuous extraction must be started within 5 days of VTSR. Analysis: 40 days from start of extraction |

## Footnotes

[1] Use only in the presence of residual chlorine.

[2] Optionally, all samples may be tested with lead acetate paper before pH adjustment in order to determine if sulfide is present. If sulfide is present, it can be removed by the addition of cadmium nitrate powder until a negative spot test is obtained. The sample is filtered and then the NaOH is added to pH 12.

[3] Filter samples immediately on-site before adding preservatives for dissolved metals.

[4] Applies to samples to be analyzed by GC, LC, or GC/MS for specific compounds.

[5] Sample receiving no pH adjustment shall be analyzed within seven days of sampling.

[6] The pH adjustment is not required if acrolein will not be measured. Samples for acrolein receiving no pH adjustment shall be analyzed within three days of sampling.

[7] When the extractable analytes of concern fall within a single chemical Category, the specified preservative and maximum holding times shall be observed for optimum safe guard of sample integrity. When the analyses of concern fall within two or more chemical categories, the sample may be preserved by cooling to four (4) degrees Celsius, reducing residual chlorine with 0.008% $Na_2S_2O_3$, storing in the dark and, for pesticides only, adjusting the pH to 6-9.Samples preserved in this manner may be held for seven days before extraction and 40 days after extraction. Exceptions to this optional preservation and holding time procedure are noted in reference 1 (regarding the requirement for thiosulfate reduction of residual chlorine), and references 8 and 9 (regarding the analysis of benzidine).

[8] Extracts may be stored up to seven days before analysis if storage is conducted under an inert (oxidant-free) atmosphere.

[9] For the analysis of diphenylnitrosamine, add 0.008% $Na_2S_2O_3$ and adjust pH to 7-10 with NaOH within 24 hours of sampling.

[10] The pH adjustment may be performed upon receipt at the environmental laboratory and may be omitted if the samples are extracted within 72 hours of collection. For the analysis of aldrin, add 0.008% $Na_2S_2O_3$.

[11] Method 1631 Revision B: Mercury in Water by Oxidation, Purge and Trap and Cold Vapor Atomic Fluorescence Spectrometry is required. Samples may be shipped to laboratory unpreserved if collected in fluoropolymer bottles, filled to top with no headspace, capped tightly, and maintained at 4°C from time of collection until preservation. The samples must be acid preserved within 48 hours after sampling.

[12] First use of samples shall begin within 36 hours of collection. For storm water discharges, first use of the sample shall begin within 48 hours of collection.

[13] Once collected if the assay can not begin within 8 hours then the sample must be frozen. Once defrosted, the sample can be held at 4°C until the assay begins. The assay must then be done the day that the sample is defrosted.

[14] Elution, concentration and the application of the purified sample to the slide must be completed in one work day. The sample must be stained within 72 hours of the application of the purified sample to the slide. Up to 7 days are permitted between sample staining and examination.

# Appendix C-2: Required Preservation, Container, and Maximum Holding Times for Air Samples

## Required Preservation, Container, and Maximum Holding Times for Air Samples

| Parameter | Preservation | Container | Maximum Holding Times |
|---|---|---|---|
| Hexavalent Chromium | Cool 4°C ± 2°C | 47 mm PVC filter and cellulose backup pads loaded in a Federal Reference Method (FRM) type cassette with holder<br><br>Place sample cassette assemblies in a clean Ziploc ® bag | The laboratory SOP specifies holding times only for samples from chromium plating or paint operations. A maximum holding time of 30 days from sample collection which conforms to NJDEP requirements for hexavalent chromium in non-aqueous samples will be used. In general filter samples will be analyzed and reported within 5 business days of collection. |
| Particulate Matter ($PM_{10}$) | None, ambient temperature | 47 mm $PM_{10}$ filter in static, dissipative plastic petri dish slides for particulate filter transit and/or storage | None |

AECOM

**FIELD CHANGE NOTIFICATION**

**PPG - NON-RESIDENTIAL SITES**

**CHANGE NUMBER #20: GW IRM Phase II O&M Monitoring (Revision 2)**

| | |
|---|---|
| ACO Site Number: Site 114 | Site Name:<br>Garfield Avenue Group Sites |

| | | |
|---|---|---|
| Requesting Party:<br>Trevor King, AECOM<br>Richard Feinberg, PPG | Signature:<br>Trevor King | Date:<br>07/22/2020 |

**Change Description:**

Peristaltic pumps are proposed in lieu of bladder pumps to collect groundwater samples for the baseline, operational, and treatment monitoring events that are being conducted to support the Groundwater (GW) Interim Remedial Measure (IRM) Phase II activities at Garfield Avenue (GA) Group Site 114. The proposed change is a deviation from the groundwater sampling procedures specified in the *Field Sampling Plan/Quality Assurance Project Plan, Non-Residential and Residential Chromium Sites, Hudson County, New Jersey* (AECOM, 2010) (June 2010 FS/QAPP), as updated. Consistent with the FS/QAPP and the New Jersey Department of Environmental Protection Field Sampling Procedures Manual, Chapter 6.9, water quality indicator parameters (WQIP) will be collected and low-flow stabilization data will be recorded before groundwater sample collection. If all WQIP stabilize within one hour of commencement of purging, a groundwater sample will be collected. However, if turbidity stabilization is attained but the remainder of the WQIP do not stabilize, purging will continue for up to one hour after the commencement of purging and a groundwater sample will be collected. Note that this duration is less than the four hours mentioned in the FS/QAPP (Section 7.3.1.1).

The analytical datasets generated during the baseline, operational, and treatment sampling events will not be used for New Jersey Department of Environmental Protection (NJDEP) compliance purposes; the data will be used to evaluate the progress and effectiveness of the GW IRM Phase II remediation system.

**Reason for Change:**

At the present time, the subcontractor and the construction schedules are at the stage where down-well equipment (e.g., extraction well pumps, transducers, injection drop pipes, etc.) associated with the GW IRM Phase II remedial system is being installed. The down-well equipment will interfere with sample collection practices that use bladder pumps. The use of bladder pumps during baseline, operational, or treatment monitoring would cause an approximate delay of two- to four-weeks per sampling event in the GW IRM Phase II construction schedule.

To keep the GW IRM Phase II construction activities on schedule, and recognizing that peristaltic pumps are an acceptable means of collecting groundwater samples for constituents other than volatile organic compounds, it is recommended that peristaltic pumps be used instead of bladder pumps. Future compliance sampling will be performed consistent with the procedures specified in the approved June 2010 FS/QAPP, as updated.

**Implementation Schedule:**

Baseline groundwater sampling activities commenced on March 16, 2020 and 183 wells were sampled using peristaltic pumps. One additional well will be sampled when the field activities resume.

Subject: RE: FCN-020: Field Change Notification GW IRM Phase II O&M Monitoring

Weston has reviewed Field Change Notification #20: *GW IRM Phase II O&M Monitoring* dated 3/9/20 (FCN#20) submitted by the email below, and discussed our review with the New Jersey Department of Environmental Protection (Department). The proposed field change is acceptable conditioned on the comments provided herein. PPG may move forward with implementation of the planned baseline groundwater IRM #2 baseline sampling program concurrent with revising FCN#20 to incorporate these comments for the record.

1. Change Description: The change description should state the change is being made from the groundwater sampling procedures specified in the approved June 2010 Field Sampling / Quality Assurance Project Plan (FS/QAPP). Also state water quality parameter data collection will be performed and stabilization achieved consistent with the FS/QAPP.

2. Reason for Change, 2nd paragraph, last sentence: Revise the sentence to *"Future compliance sampling will be performed consistent with the procedures specified in the approved June 2010 FS/QAPP."*

Team –

Please find attached, the *Field Change Notification #20: GW IRM Phase II O&M Monitoring* for your review and concurrence.

As noted in the attached, the baseline monitoring being conducted to support the Groundwater Interim Remedial Measure Phase II activities at the Garfield Avenue Group Sites is scheduled to begin on March 16, 2020.

Therefore, kindly provide your concurrence on the revised sampling approaching described in the attached by March 10, 2020.

Thank you,
Ray

AECOM

**FIELD CHANGE NOTIFICATION**

**PPG - NON-RESIDENTIAL SITES**

**CHANGE NUMBER #22: Phase III Groundwater IRM Baseline and O&M Monitoring**

| | |
|---|---|
| ACO Site Number(s): Site 114, Site 132, Site 137, Site 143, Site 199, Carteret Avenue, Halladay Street North, Pacific Avenue, Forrest Street, Former Halsted Property, Forrest Street Properties, Eden Wood Properties. | Site Name:<br>Garfield Avenue Group Sites |

| | | |
|---|---|---|
| Requesting Party:<br>Joseph M. Luty, PE, AECOM<br>Richard Feinberg, PPG | Signature:<br>  | Date:<br>08/30/2021 |

**Change Description:**

The following modification to the groundwater sampling program to support the Phase III Groundwater Interim Remedial Measure (IRM) activities at Garfield Avenue (GA) Group Sites is being proposed:

Peristaltic pumps are proposed in lieu of bladder pumps to collect groundwater samples for the baseline, operational, and treatment monitoring events. Consistent with the Field-Sampling Plan/Quality Assurance Project Plan (FSP/QAPP) for the GA Group Sites and the New Jersey Department of Environmental Protection (NJDEP) Field Sampling Procedures Manual (FSPM), Chapter 6.9, water quality indicator parameters (WQIP) will be collected and low-flow stabilization data will be recorded before groundwater sample collection. If all WQIP stabilize within one hour of commencement of purging, a groundwater sample will be collected. However, if turbidity stabilization is attained but the remainder of the WQIP do not stabilize, purging will continue for up to one hour after the commencement of purging and a groundwater sample will be collected. Note that this duration is less than the four hours mentioned in the FS/QAPP (Section 7.3.1.1).

This proposed change is a deviation from the groundwater sampling procedures specified in the *Field Sampling Plan/Quality Assurance Project Plan, Non-Residential and Residential Chromium Sites, Hudson County, New Jersey* (AECOM, 2010) (June 2010 FS/QAPP), as updated.

The analytical datasets generated during the baseline, operational, and treatment sampling events will not be used for compliance with the NJDEP Groundwater Quality Standards; but rather will be used to evaluate the progress and effectiveness of the Phase III IRM remediation system.

**Reasons for Change:**

Down-well equipment (e.g., transducers, injection drop pipes, etc.) associated with the Phase III IRM system will interfere with sample collection practices that use bladder pumps. The use of bladder pumps during baseline, operational, or treatment monitoring would cause an approximate delay of two- to four-weeks per sampling event in the Phase III IRM construction schedule.

To keep the construction activities on schedule and recognizing that peristaltic pumps are an acceptable means of collecting groundwater samples for constituents other than volatile organic compounds, it is recommended that peristaltic pumps be used instead of bladder pumps. Future compliance sampling (i.e., post-treatment performance monitoring) will

be performed consistent with the procedures specified in the approved June 2010 FS/QAPP, as updated.

**Implementation Schedule:**

Baseline groundwater sampling activities at select well locations using bladder pumps was completed between June 9 and July 9, 2021, to collect analytical data to support an adaptive management approach to guide the installation of additional remediation and/or monitoring wells. Baseline sampling of the remainder of the Phase III IRM wells, using peristaltic pumps, is expected to be conducted between August and September 2021.

| Subject: | [EXTERNAL] RE: [EXT]:PPG GA Group Groundwater - Groundwater RI Bedrock Investigation |

On behalf of the New Jersey Department of Environmental Protection (Department), please see the comments herein related to PPG's January 25, 2022 bedrock groundwater remedial investigation (RI) update provided per the email below, as supplemented by a meeting held on February 2, 2022 where AECOM presented to the Department PPG's proposed scope of work to complete the delineation of the chromium impacts in bedrock groundwater.

1. At the time of the February 2, 2022 meeting, the specific capacity testing and surface geophysics results were pending and not available for discussion. Since PPG is implementing the bedrock groundwater RI "at risk", the Department requests that PPG provide the specific capacity testing and surface geophysics results as soon as they are available to support conformance to the Master Schedule.

2. The data and information provided by PPG did not include figures showing the distribution of chromium in plan or cross-sectional views although such figures were used by AECOM during the February 2, 2022 meeting. The Department requests that figures portraying the currently known extent of bedrock contamination in plan and cross-sectional views be provided to the Department ahead of the bedrock groundwater RI Report to facilitate the Department's on-going understanding of the extent of contamination in bedrock.

3. During the February 2, 2022 meeting, the Department emphasized the requirement that any existing or proposed monitoring well to be used for delineation purposes must intersect the same fractures as the contaminated bedrock monitoring well. For example, PPG has proposed 114-MW6D to delineate contamination present in 114-MW52D. However, based on the site-specific bedrock strike and dip, 114-MW6D does not intersect the same fractures as 114-MW52D. Therefore, 114-MW6D cannot be used to delineate contamination present in 114-MW52D, and installation of a delineation well to the northeast of 114-MW52D (along strike), biased to the fracture(s) with the highest chromium concentration, would be required as part of the scope of work for the next mobilization.

4. As observed on a figure depicting cross-section B-B' presented by AECOM during the February 2, 2022 meeting, hexavalent chromium exceeding 50,000 ug/l is present in the Lockatong formation at deepened borehole 114-MW66D. However, the highly contaminated fractures at 114-MW66D were

not intersected in the downdip direction at 114-MW61D which was advanced through the diabase and into the Lockatong formation. Furthermore, based on the site-specific bedding dip, the scope of work as proposed does not intersect the highly contaminated fractures in 114-MW66D at a downdip location. Ultimately, delineation of the fractures with the highest chromium contamination in the downdip direction is required to complete the bedrock groundwater RI and a well in the downdip direction from 114-MW66D would be required as part of the scope of work for the next mobilization.

Thank you.

Subject: [EXT]:PPG GA Group Groundwater - Groundwater RI Bedrock Investigation

**CAUTION:** ***External Message***

As discussed during the January 19, 2022 Principals' Call, and on behalf of PPG, AECOM is providing the following for information purposes, only:

- Attached file, which includes a table (Table 1) summarizing the bedrock well installation and sampling data from the Sept-Dec 2021 Bedrock Field Investigation and a figure (Figure 1) showing the bedrock well locations; and
- Summary of additional Bedrock Field Investigation to occur in 2022 (below).

*2022 Bedrock Field Investigation Summary*

Bedrock Well Installation, Development, and Geophysics: One new bedrock well (114-MW73D) will be installed on Site 132 using sonic and/or conventional drilling methods to provide horizontal delineation in the Lockatong Formation along the predominant northeast-southwest trending bedding plane strike south of impacted well 114-MW72D. No sooner than 24 hours following installation, the newly installed bedrock well will be developed using techniques in accordance with the NJDEP's Field Sampling Procedures Manual (NJDEP, 2005) (FSPM) and PPG's Field Sampling Plan/Quality Assurance Project Plan (FSP-QAPP) (AECOM, 2010). Geophysical logging will be performed within the open borehole

interval of the newly installed bedrock well. The same suite of borehole geophysics will be performed at each location as was conducted for the Sept-Dec 2021 Bedrock Field Investigation.

Groundwater Elevation Gauging and Sampling: No sooner than 14 days following well development, the newly installed open hole bedrock well will be sampled using low-flow sampling protocols as defined in the NJDEP FSPM and the FSP-QAPP. Groundwater samples will be submitted to a NJ-certified laboratory for analysis of total phase Cr+6 and total phase Cr. Field parameters, including depth to water, pH, ORP, dissolved oxygen, temperature, specific conductivity, and turbidity will be recorded on field data collection sheets and groundwater samples will be collected upon stabilization of these parameters as defined in the FSP-QAPP. Upon completion of the groundwater sampling program, the collected data will be validated. Prior to sampling activities, a synoptic round of groundwater elevations will be collected from the newly installed bedrock well and existing bedrock wells to evaluate bedrock groundwater potentiometry. The wells targeted for groundwater elevation gauging include: 114-MW16B, 114-MW4D, 114-MW52D, 114-MW57D, 114-MW61D, 114-MW66D, 114-MW6D, 114-MW7D, 114-MW71D, 114-MW72D, and 114-MW73D.

Resampling of Bedrock Well 114-MW61D: The open borehole interval at well 114-MW61D was extended to 135 feet (ft) below ground surface (bgs) in November 2021 to complete horizontal delineation of groundwater impacts at the contact between the diabase and the Lockatong Formation, and within the Lockatong Formation, in the area down-dip (along Lockatong Formation bedding) of well 114-MW66D where groundwater impacts have been identified in the Lockatong Formation. Due to instability of the borehole (highly weathered/fractured rock causing borehole cave-in), well 114-MW61D was completed with 2-inch polyvinyl chloride (PVC) casing and a 25-foot section of 10-slot PVC screen set from 110 to 135 ft bgs. Based on samples collected from well 114-MW61D in February 2021 (from 88 to 110 ft below top of well casing [btwc]) and in December 2021 (from 117 to 135 ft btwc), all intervals sampled exhibit Cr concentrations below the GWQS for Cr of 70 µg/L except for one field duplicate sample collected at 130.8 ft btwc where Cr was detected at 88.3 µg/L. Based on these findings, the result for the 130.8 depth interval seems anomalous and this interval will be re-sampled and compliance averaging will be used to complete delineation at this location. Well 114-MW61D will be sampled at 130.8 ft btwc using low-flow sampling protocols as defined in the NJDEP FSPM and the FSP-QAPP. Two samples will be collected, one month apart, to allow for compliance averaging. Groundwater samples will be submitted to a NJ-certified laboratory for analysis of total phase Cr. Field parameters, including depth to water, pH, ORP, dissolved oxygen, temperature, specific conductivity, and turbidity will be recorded in field data collection sheets and groundwater samples will be collected upon stabilization of these parameters as defined in the FSP-QAPP.

Multi-port Water FLUTe™ System Installation: Multi-port Water FLUTe™ systems will be installed at bedrock wells 114-MW52D, 114-MW66D, and 114-MW72D to conduct depth-discrete multilevel groundwater sampling within the boreholes to complete vertical delineation at these locations. Previously collected data at well 114-MW52D suggested that Cr-related impacts extended throughout the length of the open borehole, based on samples collected in February 2021 from 81 to 105 feet below top of well casing (ft btwc) which exhibited Cr concentrations ranging from 42,200 to 46,500 micrograms per liter (µg/L). However, a sample collected at 114-MW52D in December 2021 from a depth of 104 ft btwc, after installation of a packer at 100 ft btwc to isolate the bottom 5-foot section of the open borehole, exhibited a Cr concentration of 5,630 µg/L demonstrating that Cr concentrations attenuate with depth within the borehole. During sampling of the packered interval, it was difficult to fully purge the isolated portion of the open borehole due to the extremely low yield for this portion of the well (heat pulse flow meter logging showed no measurable flow in the borehole below 90 feet). Therefore, it is likely that the sample collected at 104 ft btwc exhibited residual Cr concentrations associated with impacted groundwater remaining within the borehole which could not be removed during purging. A similar condition is expected at wells 114-MW66D and 114-MW72D, where heat pulse flow meter logging showed no measurable flow at 114-MW66D below 125 feet and no measurable flow at 114-MW72D below 106 feet. The Multi-port Water FLUTe™ systems will be installed to allow for the collection of groundwater samples at fracture intervals identified within the boreholes based on geophysical logging and at the bottom of each borehole. The collected samples will be submitted to a NJ-certified laboratory for analysis of total phase Cr+6 and total phase Cr and the data will be validated.

Contingency Bedrock Well Installation to Achieve Vertical Delineation: Should the Multi-port Water FLUTe™ program not achieve vertical delineation, one new bedrock well will be installed next each of the existing bedrock wells 114-

MW52D, 114-MW66D, and 114-MW72D for a total of three new bedrock wells (114-MW74D, 114-MW75D, 114-MW76D). Proposed contingency well locations are depicted on Figure 1.

Data Evaluation: The data generated will be evaluated. If the evaluation indicates that vertical and horizontal delineation of CCPW impacts to bedrock groundwater are complete, then PPG will prepare an addendum to the revised groundwater RI report to document the investigation activities and associated findings and conclusions.

Anticipated Schedule:

- Installation of the Multi-port Water FLUTe™ System is expected in March 2022;
- Installation of new bedrock wells, geophysics, elevation gauging and groundwater sampling are expected to occur between April and June 2022;
- Laboratory analysis and data validation are expected to occur in July 2022; and
- Preparation and submittal of the RIR Addendum for Bedrock is expected by the end of August 2022.

# Meeting Summary

**Meeting name**
GA Group
Groundwater Meeting

**Meeting date**
October 19, 2023

**Time**
10:00 AM – 2:30 PM

**Location**
AECOM Piscataway, NJ and Microsoft Teams

**Prepared by**
PPG

**Internal Reference:**
GW-116
PN# 60704509

**Attendees**
Ron Riccio, Site Adminstrator
Nancy Colson, Site Administrator Assistant
Jim Ray, Assistant Site Administrator (virtual attendee)
Ian Curtis, NJDEP
Dave Van Eck, NJDEP
Dave Spader, Endpoint (virtual attendee)
Peter Sorge (on behalf of Hampshire)
Prabal Amin, Weston Solutions
Ralph Costa, Weston Solutions
Jody Overmyer, PPG
Matt Schnobrich, Arcadis
Mark Pietrucha, Woodard & Curran
Shannon Gleason, AECOM
Frederik Schuele, AECOM
Joseph Luty, AECOM

---

The meeting commenced at approximately 10:15 AM in AECOM's Piscataway office with introductions of the attendees. Virtual attendees joined via Microsoft Teams.

The Site Administrator, Ron Riccio, provided introductory comments summarizing several letters, emails, meetings, and reports that have been provided recently regarding the investigation and remediation of groundwater at the Garfield Avenue (GA) Group Sites:

- Letter dated May 5, 2023 from Assistant Commissioner David Haymes (NJDEP) regarding groundwater at the GA Group Sites that identified 12 items which must be addressed to the Department's satisfaction in order for the agency to approve a Groundwater Remedial Action Report (RAR) for the overburden and bedrock aquifer zones and PPG's application for a Remedial Action Permit – Ground Water (RAP-GW).
- Technical meeting on June 8, 2023 regarding the delineation of chromium (Cr) impacts within the bedrock water-bearing zone and the progress of the groundwater remedy at the GA Group Sites.
- Email dated June 16, 2023 from the 2009 Partial Consent Judgment (JCO) Site Administrator's Independent Technical Consultant, Weston Solutions, Inc. (Weston) requesting four items, in writing, from PPG "to help resolve some of the technical issues discussed related to the March 2023 Addendum to Groundwater Remedial Investigation Report [RIR] and Groundwater Remedial Action Work Plan [RAWP] for Bedrock Water-Bearing Zone."
- Letter dated June 30, 2023 from Mark Pietrucha, LSRP, to Assistant Commissioner Haymes providing responses to the Weston June 16, 2023 email and responses to four of the items in the Department's May 5, 2023 letter and requesting Department approval of the March 2023 Addendum to Groundwater RIR and Groundwater RAWP for Bedrock Water Bearing Zone.
- Transmittal dated September 8, 2023 from PPG providing the draft Groundwater RAR for the GA Group Sites, as well as responses to the remaining eight items in the Department's May 5, 2023 letter and a table indicating where each of the 12 items (identified in the Department's May 5, 2023 letter) are documented in the draft Groundwater RAR submittal.
- Email dated September 8, 2023 from Ron Riccio providing sub points developed by Weston that elaborate on each of the 12 items raised in the Department's May 5, 2023 letter.
- Transmittal dated October 13, 2023 from PPG providing, in red colored text (i.e., redlined), responses to the sub points developed by Weston (provided via email on September 8, 2023), and noting those comments that are considered resolved and require no further discussion with NJDEP.

Ron Riccio summarized that the purpose of this meeting is to discuss and resolve items in the Department's May 5, 2023 letter. At the conclusion of the meeting, Mr. Riccio expects to report progress on the resolution of the items identified in the Department's May 5, 2023 letter to the Superior Court. Mr. Riccio requested that all parties make a good-faith effort to resolve the issues to avoid the potentially significant delays that could result if the Parties reach an impasse and need to re-engage the judge.

Discussions during the meeting were facilitated by the attached presentation developed by PPG. It should be noted that due to time constraints all items included in the presentation were not presented by PPG and/or discussed by the group. Highlights, decisions, and actions from items discussed during the meeting are summarized below by key topic.

**RIR for the Bedrock Water Bearing Zone:**

- Weathered Bedrock:
  - PPG agreed to install one additional monitoring well at the location agreed upon by NJDEP/Weston in weathered bedrock in an effort to complete horizontal delineation of total chromium (Cr) in weathered bedrock groundwater.
  - NJDEP agreed to extend the 70 parts per billion (ppb) Cr isocontour to the vicinity of wells with Cr concentrations below 70 ppb.
  - NJDEP and PPG agreed that, should Cr not exceed 70 ppb in the sample collected from the newly installed well at the agreed upon location extending the 70 ppb isocontour as described above will meet NJDEP's requirement for "clean point" delineation within the weathered bedrock and does not impact the already completed delineation in the competent bedrock to the east of 114-MW66D.
- Competent Bedrock:
  - PPG agreed to install two monitoring wells in competent bedrock at locations agreed upon by NJDEP/Weston to evaluate potential hydraulic connection with 114-MW66D and provide data to triangulate groundwater flow direction within competent bedrock.
  - If the newly installed wells are determined to not be hydraulically connected to existing well 114-MW66D, NJDEP will accept a variance from the requirement to demonstrate the presence (or absence) of hydraulic connection between competent bedrock wells and confirm groundwater flow direction in competent bedrock.
  - It was noted that PPG objects to the technical basis on which the NJDEP is requesting these two additional competent bedrock wells, which are in an area that PPG has identified as contaminated.
- Figures depicting the agreed upon locations of these proposed wells will be provided by PPG to all parties.

**RAWP for the Bedrock Water Bearing Zone:**

- Weston stated that the NJDEP does not accept the proposed remedy for the bedrock water-bearing zone.
- PPG offered the following response:
  - Reagent distribution is being observed in weathered bedrock from injections in the overburden.
  - The Cr plume is stable and not expanding.
  - There are no impacts to human health or ecological receptors.
  - Institutional controls are in place (i.e., Classified Exception Areas).
  - Near-term changes in Cr concentrations are expected and long-term monitoring will demonstrate remedy effectiveness. Time is needed to let the remedy work.
- Prabal Amin suggested that Cr(VI) concentrations of 1,000 ppb would need to be achieved before the Department would consider transition to a monitored natural attenuation (MNA) remedy for groundwater to be appropriate.
- Mark Pietrucha responded acknowledging that the approved remedy for overburden groundwater targets areas with Cr(VI) greater than 1,000 ppb for treatment - but does not require Cr(VI) concentrations to be below 1,000 ppb in order to transition to MNA. He further indicated that NJDEP MNA guidance indicates "for inorganics, MNA is most effective when immobilization [or plume stabilization] is demonstrated to be occurring." NJDEP MNA guidance does not speak to the need for decreasing trends or achieving a certain concentration in order for MNA to be an appropriate remedy for inorganics. In addition, PPG is aware of several other Hudson County Chromate sites where Cr(VI) concentrations in groundwater exceed 1,000 ppb and NJDEP has approved a MNA remedy and issued a MNA category Remedial Action Permit for Groundwater.

- Frederik Schuele indicated that the active remedy implemented in the overburden must be given time to work. Based on the data collected to date, effects of the active remedy are being observed in bedrock. Therefore, active treatment in bedrock is not necessary because the remedial goal of plume stability in bedrock is being achieved.

**Groundwater RAR for GA Group Sites (all water-bearing zones)**

- Matt Schnobrich indicated that variable permeability and hydraulically isolated intervals are present in the overburden throughout the GA Group Site area and that the NJDEP-approved RAWP accommodates management of these areas via enhanced attenuation/establishment of reactive zones in the surrounding higher permeability materials which will be demonstrated by/through long-term monitoring.
- Matt shared a video available from Colorado State University illustrating the effects of matrix diffusion in overburden soils, and further explained how these effects are present at the site.
- Matt summarized that, overall, 85% of the monitoring wells at the GA Group Sites exhibit hexavalent chromium concentrations less than 1,000 micrograms per liter and that remedy operations are still ongoing in the Phase III area.
- PPG has addressed the items raised in the Department's May 5, 2023 letter in the draft Groundwater RAR submitted on September 8, 2023. In its cover letter transmitting the report, PPG included a table indicating where each of the 12 items (identified in the Department's May 5, 2023 letter) are documented in the draft Groundwater RAR submittal.
- In accordance with the Master Schedule milestones, NJDEP review of the draft Groundwater RAR is expected by December 4, 2023.
- NJDEP and Weston will complete review of the draft Groundwater RAR by the master schedule milestone date, and, as per the request of Ron Riccio, will consider that PPG's experts have provided a thoughtful, technically accurate, and regulatorily compliant document, and rather than pointing out where PPG's approach is different than the one they may take, consider if PPG's approach is suitable in achieving remedial goals and objectives and is protective of human health and the environment.
- Ron Riccio suggested that rather than communicating in writing only, technical experts from NJDEP and PPG should discuss technical or clarifying questions in one-on-one conversations during the review process.

During the meeting, Ron Riccio asked NJDEP to identify the standard by which the Groundwater RAR will be compared against to determine acceptability by the NJDEP. This question was asked in the context of the potential to re-engage the judge should there be an impasse between the Parties as the judge will ask what is the standard that PPG's remediation is being held/compared to.

- NJDEP indicated the Technical Requirements for Site Remediation (the "Tech Rule") provides the standard, which are supported by technical guidance documents published by the Department. Mr. Riccio inquired if the guidance is the standard, to which NJDEP responded that guidance provides helpful interpretation of the Tech Rule, but the Tech Rule provides the standard.
- Mark Pietrucha clarified that the Tech Rule is provided in N.J.A.C. 7:26E, and that while it is the standard, the Tech Rule itself indicates that remediation can vary from the requirements set forth in N.J.A.C. 7:26E when the remediation is demonstrated to be protective of human health and the environment. Mr. Pietrucha further indicated that precedence established by Department decisions and approvals at other sites in NJ can also guide the standard, to which Mr. Riccio agreed.
- Mr. Riccio inquired if the Department's May 5, 2023 letter listed all the items that need to be addressed by PPG in accordance with the NJDEP standard to achieve acceptance of the Groundwater RAR, and the NJDEP concurred.

Ron Riccio inquired if Peter Sorge, on behalf of the redeveloper, had any remarks. Mr. Sorge offered the following comments:

- In his opinion, PPG has conducted a tremendous remediation of groundwater at the GA Group Sites.
- A lot has been accomplished: a lot of materials have been injected into the subsurface and Cr concentrations have been reduced significantly.

- Mr. Sorge opined that PPG's current delineation of groundwater impacts in the bedrock water-bearing zone and their proposed remedy for the bedrock water-bearing zone are adequate and appropriate.

Ron Riccio thanked the attendees for their participation in the meeting. He concluded that his report to the Superior Court with respect to progress on resolution of the items identified in the Department's May 5, 2023 letter will be prepared after the Department has reviewed the Draft Groundwater RAR.

Mr. Riccio's closing remarks noted that he was impressed with the credentials and stature of all of the experts representing NJDEP, Jersey City, and PPG. He pointed out that the various expert opinions were, in his view, offered in good faith and reflected reasoned differences of technical opinions based on knowledge, training, and experience. He stressed that the experts' differences should not be seen as if the context is an adversarial court proceeding but, rather, as a collaborative process working towards a common goal shared by all to achieve effective, efficient, and safe groundwater remediation that protects the public health, safety, and welfare. To achieve the common goal Mr. Riccio suggested that NJDEP's experts (Ian Curtis and Dave Van Eck as well as Weston's experts Ralph Costa and Prabal Amin who assist both NJDEP and the Site Administrator) and Jersey City's expert (Dave Spader) work closely and collaboratively with PPG's experts (Jody Overmyer, Mark Pietrucha, Matt Schnobrich, Shannon Gleason, Frederik Schuele, and Joseph Luty) in reviewing/responding to PPG's draft groundwater RAR for the GA Group Sites. Mr. Riccio suggested that the close coordination and collaboration include, but not be limited to, as needed in person meetings, as needed virtual meetings, and as needed phone discussions between and among all the experts prior to issuance of written comments by NJDEP/Weston to the RAR. Mr. Riccio asked if anyone disagreed with his suggestion. No one disagreed with his suggestion, and all endorsed it as a sensible and efficient way to proceed.

The meeting concluded at 2:30 PM.

| Subject: | PPG- GAG GW Bedrock Well Locations |
| Attachments: | Figure 1 - Proposed Weathered Bedrock Well.pdf; Figure 2 - Proposed Competent Bedrock Wells.pdf |

As discussed during the Oct 19, 2023 meeting regarding groundwater at the Garfield Avenue Group Sites, PPG has agreed to the following:

- Installation of one monitoring well (114-MW75WR) in weathered bedrock at the location shown on Figure 1 to complete horizontal delineation of total chromium (Cr) in weathered bedrock groundwater.
- For the weathered bedrock, PPG is proposing to interpret the Cr isoconcentration contours as depicted on Figure 1. In doing so, PPG is extending the 70 parts per billion (ppb) Cr isocontour to the vicinity of wells with Cr concentrations below 70 ppb. As discussed during the meeting, this meets the requirement for "clean point" delineation within the weathered bedrock and does not impact the already completed delineation in the competent bedrock to the east of 114-MW66D.
- Installation of two monitoring wells (114-MW73D and 114-MW74D) in competent bedrock at the locations shown on Figure 2 to evaluate potential hydraulic connection with 114-MW66D and provide data to triangulate groundwater flow direction within the competent portion of the Lockatong Formation.

Frederik Schuele reviewed the proposed well locations with Ralph Costa via teleconference on Oct 25, 2023, during which Ralph Costa concurred with the locations presented on Figures 1 and 2.

As discussed during the Oct 19, 2023 meeting, if wells 114-MW73D and 114-MW74D are determined to not be hydraulically connected to 114-MW66D, no additional investigations will be required by NJDEP to further demonstrate the presence (or absence) of hydraulic connection between the bedrock wells completed within the Lockatong Formation.

As also discussed during the Oct 19, 2023 meeting, PPG does not understand the technical basis for the two additional competent bedrock wells in an area that PPG has identified as contaminated, but PPG is agreeing to the installation in order to satisfy the Department's request. As such, PPG is not agreeing to conduct further "step-out" explorations from proposed wells 114-MW73D and 114-MW74D.

Report Suspicious

I was hoping to discuss the issue with Ralph, but he had been preoccupied with finalizing the RAR comments, and he is on vacation for the remainder of December. (Today is my last workday as well until January 2nd.)

The two proposed weathered bedrock replacement well locations are acceptable to the Department. The main concern is that they be installed in a manner that prevents the creation of a migration pathway for any DNAPL that may be encountered.

Dave

Hi Dave. Checking in on status of review of the proposed locations for the two replacement weathered bedrock wells (yellow highlighted item below). Are you able to provide an update?

Thanks!

Subject: PPG GA Group Sites Groundwater - Low Permeability Information

Hi Dave. Thank you for taking my call last week regarding groundwater at the Garfield Avenue Group sites. As a follow up to that call, attached please find two PDF files which were shared and discussed with NJDEP and other stakeholders in February of 2021. These materials were developed to facilitate discussions regarding implementation of the groundwater remedy at the site, in particular as it relates to delivery of reagents to low-permeability soils and matrix diffusion. The February 16, 2021 file was also included in Appendix A.2 of the groundwater RAWP as an attachment to a memorandum providing responses to comments on the definition of low permeability for the site. This memorandum is also attached for your reference. Additional details regarding the implications of soil heterogeneities on contaminant fate and transport and matrix diffusion at the site are provided in Appendix E of the groundwater RIR.

Regarding the basal till, the groundwater RIR included an evaluation of permeable zones within the basal till (Appendix G) and concluded that of the approximately 390 ft of basal till logged at the site, only 21 ft consisted of sand stringers or lenses, which equates to less than 6% of the basal till. The RIR further noted that, where present, these higher permeability intervals within the basal till may serve as preferential migration pathways for Cr-impacted groundwater. I believe that this is the migration mechanism for the observation of EVO at weathered bedrock well 114-PZ-52WR. However, as discussed in the summary of hydraulic testing results provided in Appendix D of the addendum to groundwater RIR and groundwater RAWP for the bedrock water-bearing zone, the bulk permeability of the basal till, as a whole, is several orders of magnitude lower than the permeability of any sand stringers or lenses within the till. Furthermore, the permeable sand stringers or lenses are limited in lateral extent.

I found it beneficial to review these items within the context of more recent discussions related to how low-permeability soils will be managed by the remedy over the long-term.

Lastly, we also discussed the proposed locations of two replacement weathered bedrock monitoring wells. As a reminder, we are mobilizing to the site this week to initiate the drilling program and would like to receive your concurrence with our proposed locations.

Best regards,

Ralph – Regarding the requirement to demonstrate hydraulic connection between 114-MW75D and 114-MW72D, we intend to evaluate this during well development activities at 114-MW75D. We will deploy transducers in each of the FLUTe ports at 114-MW72D to monitor for hydraulic response while pumping the open borehole at 114-MW75D. This was the same approach that was successfully employed in January 2024 to demonstrate hydraulic connection between 114-MW66D and wells 114-MW73D and 114-MW74D (see Table 2 and Attachment 2 of the *Summary of Packer Testing and Hydraulic Monitoring Results* technical memorandum).
